JOURNAL OF HORTICULTURE,

COTTAGE GARDENER,

AND

HOME FARMER.

A CHRONICLE OF COUNTRY PURSUITS AND COUNTRY LIFE, INCLUDING BEE-KEEPING.

CONDUCTED BY

ROBERT HOGG, LL.D. F.L.S.

Established

in 1848.

VOLUME XX. THIRD SERIES.

JANUARY — JUNE, 1890.

LONDON:

PUBLISHED FOR THE PROPRIETOR, 171, FLEET STREET.

LONDON :
PRINTED AT THE JOURNAL OF HORTICULTURE OFFICE,
171, FLEET STREET.

TO OUR READERS.

A QUESTION we are often asked is this—Is horticulture advancing? If we take as evidence Roses and Strawberries—which now abound—the reply must be distinctly in the affirmative, for at no period was either of them so well and extensively cultivated in fields and gardens as at the present time.

We are glad also to believe that in other directions progress is being made, and we are convinced that never before was gardening so highly cherished as it is now, nor practised so well in its many branches by such a large number of persons in this country.

All this is gratifying, as though rain may spoil a few Roses and Strawberries, and frost and caterpillars decimate our fruit crops occasionally, they are only passing troubles, and the more widely and well the art of gardening is pursued the greater the pleasures and benefits to individuals who engage in it, and the greater the advantages to the general populations who enjoy what is so freely produced.

It is not only our duty but our pleasure to gather the best information that is available for distribution to the world through the JOURNAL OF HORTICULTURE, in the hope and with the object that the advance in gardening in its varied phases will be greater in the future than in the past; and we cannot adequately record our obligations to all who so willingly and ably co-operate with us in this most agreeable work.

In tendering our thanks to *all*—gardeners and amateurs—who by their talents have enriched the pages of the last completed volume of this Journal, we desire to add that seekers for information are also helpers in eliciting it, and we cannot conceive any greater pleasure than assisting young gardeners and inexperienced amateurs in moments of difficulty.

The key note of the JOURNAL OF HORTICULTURE is *usefulness*, and the desire of its conductors and staff is to be helpful to all.

INDEX.

ABERJAFRA (KEI APPLE), 132
Abutilons, hardy, 455
Acacia ovata, 137
Acer Prince Hendery, 403
Achillea (Parnica) mongolica, 492
Achilmenes Rosy Morn, 347
Adiantum 173; cuneatum, 201
Aerides, potting, 216
Agathaea coelestis, 350
Allantus glandulosa, 457
Allamandas, 301, 516; **A. Hendersoni,** culture of, 56
Allotments, 83
Alpue and herbaceous plants, 480
Alternaothenas, 231
Amaryllises for decoration, 341
Amaryllis formosissima, 172
Amateur's garden, an, 4 8
America, notes from, 63; flower culture in, 83
American nursery, Mr. Meehan's, 485
Am I in it? 214
Anemones, planting, 35; notes on, 461
Angelica culture, 271
Anracum hybrid, 227
Annua for cutting, 78; for exhibition, 502
Anthericum albo-medie pictum, 155
Anthrax coal, 508
Anthurium Schertzerianum sanguineum, 419; album maximum, 461; **M. de la Devanayse's,** 501
Antirrhinums, 162
Aphides in fruit trees, 455
Apple Chermes, destroying, 496
Apples and Osiers, 145
Apples and Pears for foam over chalk, 393
Apple trees, pruning, 164, 185; insects on, 251; summer pruning espalier, 519
Apple—Beauty of Hants, 231; **Blenheim Pippin** for profit, 191; **Bramley's Seedling,** 241; culture, 62, 275; culture, British, 38; **Gibson's Russet,** 87; **Rosemary Russet,** 88; **Golden Russet,** 131; **Golden Duke's,** 310; **Royal Somerset,** 143; **Selwood's Reinette,** 57; exports of American, 219; notes on varieties, 194, 222, 257, 295; soil and situation for, 323; soil for, 53; the flowering and flowers of, 191; their culture and uses, **Mr. Roupell's** lecture, 242; notes on, 333, 364; **Tasmanian,** 361; notes on, 397; notes on, 416; pruning and non-pruning, 422; **Ecklinville Seedling** on Crab, 423
Apricots, culture of, 107, 295
Aquarium (Royal) Shows, 153, 366, 429
Aralla Sieboldi, 289
Arenaria gothica, 175
Arisema speciosum, 243
Artichokes, Jerusalem, 163
Arums for market, 271
Ash, Weeping, at Nostell Priory, 301
Asparagus, planting and value of crop, 270
Aspidiatrias, dividing, 569
Auricula and Pinnula Society's show, 344
Auricula Society (National) Northern Show, 330
Auriculas—Magpie, Nellie Hibberd, Tonjours Gai, Lovebird, Bridesmaid, 337
Auriculas in Scotland, 160
Auriculas and shows, 383
Azaleas, hybrid, 152; mollis, 443

BALLAST, MAKING AND USING, 102
Barne de Capain, 270
Bardney, presentation to Mr., 400
Barilla industry, 220
Bassett, a hanging, for a conservatory, 300

Patemaunia Walli, 491
Path spring show, 26, 457
Beans, Kidney, forcing 8; **Harcots,** 270
Bedding plants, notes on, 23; preparing, 349; sub-tropical, 486
Bees—Young bees in December; **Hallamshire glass sections,** 19; notes on, 18, 55, 62, 248, 289, 350, 391; hints to beginners, 33, 77, 97, 129, 141, 208, 350, 369; royal cells, non-swarming 34; early feeding, 76; feeders, 77; bees hibernating, rearing queens, 77; winter preparation, 142; the season; stimulating bees; hiving; Punic bees; judging honey; bees carrying pollen, 682; moving, 99; feeders and feeding, 19; storing appliances, 119; honey presser, 120; queen breeding, Punic bees, 184; single cased hives, 185; straining honey, 162; ripening honey, bees for profit, artificial heat, pot arrangement, zinc for hiving box, 163; **Clover v. Heather honey,** 249; **Lanarkshire hive,** **Leicester Bee-keepers' Association,** 29; death of the **Rev. H. McLaren,** 190; origin of movable frame hives, 290; old comb, 291; seasonable notes, Punic bees, 369; spreading brood, fastening comb foundation, brace combs, carbolic acid, 310; renewing combs, 311; gathering pollen, flowers for, 230; ants in hives, Punic bees, device for hiving, 269; swarming, 229; May swarms, 269; covering hives, 370; queenless hives, foreign races, 392; bees in the north, 392; **Lanarkshire hive,** 393; supers, 411; covering hives, 412; fertile workers, renewing queens, 431; transferring, fixing foundation, 432; foul brood and its cure, 454; oil-cloths, Punic bees, supering, Dandelion honey, blending honey, the **Maitt** honey press, joining swarms, 473; feeding, hives, 495; notes on, swarming, uniting swarms, 518; preserving, dwindling, 539
Beaton greenhouses, 9
Beet, manufacture of sugar from, 132
Begonia socotrana, 9; **Tuberosa,** in Perthshire, 67; potting, 99; seed, sowing, 162; tuberous, 180; propagating, 331
Begonias (Tuberosa) certificated—Princess of Wales, Gigantea, Miss E. F. Cooper, 267; **alba plena comperta,** 409; new Tuberosa, 462 **Golden Queen and Madame Pfitzer,** 492
Bel fast Gardeners' Society, 218
Berlin, International Horticultural Exhibition at, 88, 152, 231, 340
Bertolonia Souvenir de Gand, 491
Birds in the garden, 9; and fruit trees, 75, 391; and caterpillars, 507
Birmingham Chrysanthemum Society, 46
Birmingham Gardeners' Association, 132
Birmingham show, 348
Blackberries, 241; improved, 61, 106, 118
Black Mazzard Cherry tree, 16
Bandfordia nobilis Imperialis, 498
Blenheim Pippin and other Apples, 234
Box garden at High Beach, 301
Books—Review of, "Farm Live Stock," 22; "The Garden Oracle," 26; "Rosarian's Year Book," 28; "English Vegetable Flowers in India and Ceylon," 53
Boneflour, steamed, 230

Botanic Garden and School of Botany at St. Louis, Missouri, 151
Botanic (Royal) Society—meeting of the, 45; spring show, 267; show, 347; **Floral Parade,** 403; summer show, 401; second summer show, 493
Botanical terms anglicised, 382
Botanist, a noted, 214
Botany and microscopy, Exhibition at Antwerp, 67
Botany in America, 17
Bournemouth Gardeners' Association, 282
Boussingault, the late M., 194
Bonvardias, 301, 253; culture of, 12, 106, 157; notes on, 134; for profit, 478
Brambles, 13, 48, 61; the Parsley-leaved, 152
British Fruit Growers' Association, 180, 360, 326; rules and report, 113; lecture at **Ellesmere,** 278, 378; meeting, 48
Brighton Chrysanthemum Show, 281
Broccoli, Sutton's Bonquet, 46; effect of frost on, 361; prolific, 422
Bromellads, gigantic, 483
Brussels Sprouts, 2, 0, 241; culture of the, 169
Bulb farms of Holland, 336
Bulb note, 218
Bulb show at Haarlem, 236
Bulbs, treatment after flowering, 302; at home and abroad, 318, 339, 383, 438, 483
Bulfinch, the caged, 17; antidote for, 53
Bullfinches and fruit buds, 46
Burnet, 330
Bush fruits, pruning, 74

CABBAGE PLANTS, CLUBBING, 132
Cabbages at the Wakefield Paxton Society, 175; in Jersey, 507
Cabbages and Lettuces for market, 475
Calanthes for winter, 6; value of, 270, 233; culture of, 489
Calceolaria Cloth of Gold, 367
Calceolarias at Beckenham, 468
California, a voice from, 101
Californian fruit, 154
Calla Elliottiana, 408
Camellia La Vestale, 227
Canalgie (Rumex hymenosepalum), 319
Canker in Apple trees, 178
Cannas, culture of, and varieties, 245
Carludovica palmifolia, 333
Carnations, Madame Arthur Varocque, 27; **Souvenir de la Malmaison,** 125, 104; perpetual-flowering, 154; **Mr. Cooper's prize essay on,** 39; planting, 351; **Mr. Cooper's Essay,** 410; choice varieties of, 423; calendar, 411; from seed, 488
Carnation and Picotee Union at Oxford, 193
Carnation, Souvenir de la Malmaison, 382
Carnation, culture of the, 583
Carnations and sparrows, 241
Carrots, 173; early, 18; forcing, 26
Cartier's Practical Gardener, 232
Catalpas, 457
Cateating Melons and Cucumbers, 87
Caterpillars of the winter moth and fruit trees, 95
Caterpillars on fruit trees, 117
Caterpillars and fruit trees, conference at Evesham, 204; at **Gloucester,** 395
Caterpillars, Paris green for destroying, 333; methods of destroying, 427; and science, 488
Caterpillar plague, 139, 2-2; destroying, 242; scourge, 465, 466, 475, 468

Cat, a cargo of, 131
Cattleya O'Brieniana, 25; **C. Trianae marginata,** 227; **C. Trianae fulgens,** 277; **C. Trianae,** 278; **C. Lawrenceana,** 245; **Parthenia** 441; **Lawrenceana delicata,** 461; **Mendell, Prince of Wales,** 461; **Mendell Alfred Smee,** 491
Canthflowers, forcing, 83; early, 86
Cauldwell, death of Mr. W., 231
Celosia plumosa pyramidalis, 68
Chalk for new garden, 472
Cheetham, death of Mr. James, 30
Cherry, Tobacco-leaved, 21; the black Mazzard, 16, 46; summer pruning the Morelo, 519
Cherry house, 248; work in the, 140; note on, 508
Chervil, 330
Chestnut, an early, 241
Chicory, culture of, 250, 314
Chimonanthus fragrans, 9
Chionodoxa Lucida, 460
Cholysa ternata, 341
Christie, presentation to Mr. A. D., 9
Christmas Roses, 9
Chrysanthemums—Review of the past season, dates of shows, 7; **National Society's Shows,** Lady Blanche, 31; **Moonlight,** 32; **National Society, Show meeting and Conference, Mr. Kipling's paper,** 49; notes and remembrances, 50; exhibition, a plea for small growers, 61; commercially, 71; reflexed and Anemone, 72; **Sheffield and West Riding Society's meeting and discussion, damping of blooms, new varieties,** 72; **The National Society's annual meeting, Birmingham Gardeners' Association,** 94; **Chrysanthemum, W. W. Coles,** 111; financial success of Societies, Kent County, Hull, 112; bloom damping, 110; exhibit on financial success, **Teddington and Leicester Societies,** 137; late varieties, 137; **Society (National) Centenary Festival programme,** 156; blooms, large, 156; analysis for 1883-1883, 169; for profit, 190; culture, modern, 201; late varieties; **W. W. Coles;** open air, 201; large blooms, 202; **Sheffield and Kingston Societies, presentation to Mr. Drewett,** 223; seedling at **Forest Hill,** 237; **Mrs. Carter,** 241; new varieties, 307
Cinerarias for use decoration, 153
Citrons, fingered, 581
Clark, death of Mr. James, 524
Clivias, 29; certificated—**John Laing, Bronze Queen, Surprise,** 367
Cladosporium lycopersici, 120
Clematis indivisa latata, 120; montana, 454
Clerodendron fallax and Balfourianum, 162
Clyde disaster, the late, 5
Coelogyne cristata, 6; treatment of, 185; tomentosa, 48; pandurata, 425
Cola acuminata, 330
Colour, experiments with flowers, 338
Comments and suggestions, 21
Conferences, the management and advantages of, 37
Co-operative Flower Show at the Crystal Palace, 44
Cooper, sulphate of, and lime, 368
Cornwall, exotic plants in, 381
Cranberry, culture of the, 21
Crinum brachyneura, 491
Crocuses, early, 169
Crop, the rotation of, 216
Crotons, 97, 56

Croydon Gardeners' Mutual Improvement Association, 169
Crystal Palace Shows, 130; spring show at, 283; summer show, 408
Cucumber houses, heating, 121
Cucumbers in January, 76; forcing, 161, 398; management of, 269; forcing, 516
Cucumber tree, 310
Currants, Gooseberries, and Raspberries, 512
Cydonia japonica, 237; **Moorlezi,** 478
Cyperus distans, 377
Cyprinodon Galatea majus, 5; **Schrodere,** 495; **Elliottianum,** 193; **tesselatum porphyreum,** 149; **insigne, venustum, and villosum,** 6; large specimen, **C. Elliottianum,** **C. porphyrochlamys,** **C. Germanianum,** **C. Lathamianum,** **C. cardinale,** 123; **Sedeni** and **Soierianum,** 62; cultural notes on, 150; **Nunna** and **Schomburghianum,** 27; **Aylmeri,** 459
Cytisus racemosus, 391; **securiparius Andrieux,** 408, 439

DACTYLOPIUS (MEALY BUG), 70
Daffodil Exhibition and Congress, programme of, 375
Daffodil conference—Mr. Burbridge's paper, 236; **Mr. Walker's paper,** 337
Daffodils, 313; medals for, 66; species, 321; hybrids and varieties, exhibition and conference at **Chiswick,** 321
Dahlia analysis, 1883-1889, 214
Dahlia, 302
Damson, trees falling, 331
Dandelions, destroying, 850
Death's head hawk moth, 526
Dendrobium—Juno, Luna, Macfarlanei, noble Burford variety, and xanthocentrum, 52; **D. noble varietes,** 63; **D. hybrid,** 84; **D. noble** not flowering, 164; **D. Macfarlanei,** 177; **D. Parishii,** 177; **D. Macfarlanei,** 193; **D. noble** and **Calanthes,** 193; **D. Asrasia,** 227; **D. signatum,** 227; **D. Wardianum,** **Baron Schroeder's variety,** 261; **D. atroviolaceum,** 303; **D. albosanguineum,** **D. J. mesianum,** and **D. superbum,** 313; **D. pulchellum,** 333; **Ainsworthi** 445; **Falconeri delicatum** and **Bensoniae album,** 461
Desmodium gyrans, 167
Deutzia gracilis for forcing, 147; **D. candidissima flore pleno,** 264, 297
Diminutive plants, 416
D'Ombrian, presentation to the Rev. H. H., 541
Doronicum Hartn Crane, 469

NEW YEAR'S GREETING.

TO our "most grave and reverend seigneurs," to our fair dames and gentle maidens, to our young and ardent athletes; in a word, to all our masters and mistresses, we, the old fogies and the young hands connected with "our Journal," send all brotherly greeting on the opening of another year. In the words of the old song, "we have lived and loved together," and the experience of so much kindly feeling in the past leads us to look hopefully on for the future, and as it is usual at this season to go through the process of stock-taking, so I would desire to take stock of horticulture and our connection with it during the past year.

I have already given my notes of what was noteworthy in the Rose world during the past season, and have only to add now that the Journal has worthily maintained its reputation as *par excellence* the organ of the queen of flowers; its full reports of Rose shows and meetings have shown the lively interest it has ever manifested in their culture, and I shall therefore leave the ever tempting field and go off to other pastures.

And surely first of all the state of the ROYAL HORTICULTURAL SOCIETY is that which occurs to most horticulturists. Time was when one could not but think of it with dismay, when one saw tens of thousands of pounds squandered on South Kensington for the especial delectation of the nurserymaids and babies of the neighbourhood, or for the croquet and lawn tennis players of our *jeunesse dorée*, when horticulture was the last thing thought of, and when the Commissioners of 1851 sat like a huge nightmare on it, when men were appointed as members of Council who hardly knew the difference between a Hollyhock and a Dahlia, and their Secretaries were in equally blissful ignorance, and the few horticulturists who were connected with it felt despondingly about its prospects. All that has been happily changed. It was turned out in a particularly shabby manner from South Kensington, it has been carried on on a thoroughly popular basis, the old system of cliques has been got rid of, and with it those pitfalls and quagmires into which there was ever a danger of falling by anyone who ventured to interfere for its welfare. I was in those days obliged to say some hard things about it, and got considerably "sat upon" for my pains; however, my words have proved correct, and it is no small gratification to myself, and I may add to all members of the Horticultural Club, that the first real step in the new direction was taken by it. When notice to quit South Kensington had been given I ventured to suggest that the Royal Horticultural Society should form the subject for discussion at one of our monthly meetings, and that the President should be invited. On that evening the "outside Committee" was proposed, and to its appointment may be traced, I think, many beneficial results which have since ensued. The Society has been especially fortunate in having secured the services of the Rev. W. Wilks as its Hon. Secretary, and Mr. Morris as its Honorary Treasurer. Through their means the "Transactions" have been made a valuable production, and have been brought out in good time, and everything has worn a smiling aspect—no, not everything; the Drill Hall can never bear that character, but I hope the time has now come when the horticulturists of this kingdom may provide a place for their chief Society to meet in. It is now an open secret that this is busily engaging the attention of the Council, and let us hope that the year 1890 may witness the commencement of an effort to wipe out the disgrace of the horticulturists of this kingdom, numbering

amongst their ranks men of all ranks and degrees, having no place of their own in which to hold its meetings. We do not want a place for big shows (I believe that is unnecessary), but a place where the fortnightly meetings may take place without injury either to plants or visitors.

In all directions I think we see the love of horticulture progressing. The fashions which influence it may change, but the love of flowers is so innate in our people that they must ever be popular. It is just possible that the length to which flowers at funerals have gone may cause a reaction, but flowers in one form or other we must have, and we cannot but rejoice to see so many influences at work to this end. As last year, so the three flowers which have most occupied the thoughts of gardeners have been the Orchid, Rose, and Chrysanthemum. The progress made by the latter flower has been remarkable; it lacks the refinement of Queen Rosa, or the varied charms of the aristocratic Orchid, but these are not everybody's flower as the Chrysanthemum is, cheering us in the dreary months of November and December, and bringing us with the later sorts well up to the end of the year. But while attention has been devoted to these flowers, the cultivation of all kinds of flowers, vegetables, and fruits has progressed. A great movement in the latter has taken place, and, as is usual with us, we have been rather inclined to ride the hobby to death. While there is no doubt much to be done by the better cultivation of better sorts, as has been well shown in the Fruiterers' Company's prize essay on fruit growing, yet that fruit is ever in this country to take the place of any of our other products or drive the foreigner out of our markets is a wild chimera. It must ever be an object of interest to those who desire the welfare of those around them to encourage this taste for gardening, and especially for flowers. We see how it survives in the very dreariest portions of our great city, and how tenderly the pot of "Geranium" or Mignonette is regarded, and it is quite well that it should be so. "I have been young and now am old." I have had many fancies in my day, but the love of flowers has had the main place, and I am thankful to say still survives; indeed, I think that I love them more than ever I did, although I do not think that they are the solace to me now that they used to be when I had charge of a town parish, with its manifold cares and trials and its severe work; when many a time after a day's work and worry I came home, and, turning into my garden, small and insignificant though it was, forgot the worries of the day. Did I not find, too, that if I had had to do with some crusty parishioner there was a plant that had equally bothered me? and that if I was rejoiced, on the other hand, at someone turning from evil ways under kind and loving treatment, was there not that plant which I had so carefully tended returning me tenfold for all my care? Yes, my good friends, young and old, let me earnestly press on you to love and cherish your flowers for their own sake, and for the enjoyment they can and do afford to all who treat them lovingly.

I do not think that the year has been very remarkable for the introduction of any great and startling novelties. There have been some excellent examples of the result of hybridising amongst Orchids, but there have been no such remarkable introductions as have characterised previous years. In florists' flowers, too, there have been many introductions, but I do not think that there has been any great advance; indeed in most classes of florists' flowers advance seems well nigh barred. Border Carnations are evidently largely increasing in favour, while I fancy single Dahlias have somewhat receded from the position they held. Chrysanthemums have increased in number and in size, but whether in quality may be perhaps questioned; the rage for undue size seems to me to be destructive of this quality. A great sensation has been created by the introduction from America of the curious variety Mrs. Alpheus Hardy, but it is an instance of how largely the idea of size dominates the minds of Chrysanthemum growers that already it has been condemned as not large enough. It has been described

and figured in the Journal, so there is no need to say anything about its character, but having seen it I can say that it is one greatly to be admired as curious and pretty. Begonias, especially the double varieties, have reached wonderful perfection, and the latter are now being produced better in form and with stouter stems, so that we may soon hope to see them holding themselves upright instead of hanging down or needing sticks to support them. The progress made in many of our favourites is not by "leaps and bounds," but none the less is it sure; and all honour be to those who thus try to enrich our stores and increase our enjoyment.

Amidst all that is bright and pleasant there will come over us while we are here clouds which dim this brightness, and so one in looking back over the past must think of those who are no longer with us. Heading the death roll in point of time and in the general knowledge of horticulturists we must count our late lamented friend the Hon. and Rev. J. T. Boscawen; earnest and indefatigable, moving in the higher circles of society, he was able and willing to use his influence for the benefit of horticulture. It was thus he gained for the National Rose Society the patronage of H.R.H. the Princess of Wales, and thus he was always able to influence for good the magnates of the neighbourhood wherever the Bath and West of England Show was held. This was his special work; his kindly and genial manner made him always an acceptable companion, and he has been and will be greatly missed in all future gatherings of that Society, as well as in those of horticulturists in general. Mr. Henry Curtis of Torquay has of late years been little seen amongst Rose growers, although I think few knew the Rose better or loved it more than he did. Deprived by the loss of sight of the enjoyment he once had in his flowers, he yet could speak of them with feelings of affection, and it must not be forgotten that when the National Rose Society first essayed to publish a Catalogue the Committee applied to him for the illustrations. His gentle and loving spirit found other outlets for its operations, and in doing good to those around him, showing sympathy with them in their times of need, and especially in extending to them the benefit of medical electric treatment, he spent the latter years of his life. Robert Marnock was comparatively unknown to the men of this generation. His work as a landscape gardener will long remain to mark his success, while all who knew him even slightly can but recollect him as a genial friend and companion. As long as the gardens at the Regent's Park remain they will form the most fitting monument to his memory.

And thus year after changes are ever occurring, while improvements are also ever taking place, the "work of the Journal" still goes on as successfully as ever. New writers take the place of those who have retired. It endeavours to accommodate itself to changes so far as they are in the interests of horticulture. Another year is before us; we look hopefully forward, for we are assured of the hearty goodwill of our readers. There are many ways and phrases for expressing our goodwill, but after all I know of none more expressive, more full of hearty sympathy, than that with which I now close these few words—

GOD BLESS YOU.

—D., Deal.

SULPHIDES AS FUNGICIDES.

MR. STEEL suggests that I should give him a wrinkle on the treatment of mildew of the Hollyhock. Although I have no experience in the operation of remedies on that plant, I have given some attention to the treatment of the disease in a great variety of others.

In the columns of the *Gardeners' Chronicle* of 1885 I introduced to the notice of gardeners the powerful effects of solutions of sulphide of potassium on all forms of fungoid growth. At that time I had about thirty-five years' experience in the use of the drug in the treatment of men and animals for ailments due to low forms of animal and vegetable life, but my experience of its application to plants was limited. Since then I have by many experiments fully confirmed the statement then made—that a solution of sulphide of potassium was fatal to all forms of fungus life; but the larger

experience taught me it is indispensable that the solution should be in actual contact with the fungus in order to produce its proper effect. There are many forms of fungus growth which throw off from their surfaces watery solutions, exactly as the feathers of a duck throw off water; in such a case the solution is inert, but in all cases where it comes into actual contact it is without exception fatal to the fungus. I know of no remedy for mildew on any plant which is more effectual, and generally so easy of application. A solution of half an ounce to a gallon of water is sufficiently strong, and absolutely harmless to vegetation—indeed, I have repeatedly plunged Orchids and other plants of many various kinds, soil and all, overhead in the solution without the slightest injury to them, but, on the contrary, with apparent benefit to their aftergrowth. This may be due to the potash—a necessary constituent of all plants—acting as a manure.

I know no better method of meeting the difficulty above referred to, as to contact, than the use of the sponge for wetting the surface when the fungus throws off the solution; in some cases this may be done by a very fine spray, the small globules of which will remain on the mildewed surface.

Powdered sulphur has for a long time been known as an effectual remedy for mildew, but it is unsightly on the leaves, and not so quick in action or convenient in application as sulphur in its soluble form when combined with potash, which, as a fungicide, is probably inert. There may be a difficulty in procuring the sulphide of potassium in good condition. The drug when kept, after a time decomposes and becomes inert, and druggists, if they keep it, rarely renew their stock, it having gone out of fashion as a remedy, probably owing to its offensive odour. If in good condition it will make a bright yellow solution. When there is difficulty in procuring the drug, the gardener may himself prepare another sulphide, which is equally efficient, and was frequently used by old gardeners, known to chemists as the bi-sulphide of calcium, by boiling say 1 lb. of freshly slacked lime, with an equal quantity of flowers of sulphur, in a gallon of water for a quarter of an hour. The supernatant liquor should then be poured into a bottle and kept well corked; when required mix sufficient of this with water to make a solution for use of a light yellow colour, and deal with it as with the potassium sulphide solution.

Sulphide, or more correctly ter-sulphide of potassium, formerly known as liver of sulphur, has the strong and well-known odour of sulphuretted hydrogen or of Harrogate water, and, in common with the latter, many healing qualities, due to its destructive effects on low forms of animal and vegetable life, having a beneficial action on all affections caused by them. For external application to festering and poisoned wounds to which gardeners are liable, whitlows, and many forms of skin disease in men and animals, a stronger solution than that recommended for plants, say about half an ounce to a pint of water, should be used. In many cases a single application effects what appears to be a magical cure, and it never in the slightest degree, even if many times repeated, does any injury. The sulphide solutions discolour lead and other mineral paints, but the stain is superficial, and soon wears off.—EDMUND TONKS.

FLOWER CULTURE FOR PROFIT.

IN too many instances the owners of large and small gardens alike have been ill-informed enough to imagine that the gardener in charge ought to realise sufficient from sales generally as to make the garden self-supporting. Not a few gardeners, too, were at one time imbued with the same idea, and rented the houses, kitchen and fruit garden, receiving, it may be, a fixed sum for keeping the pleasure grounds in order, furnishing the flower beds, house and conservatory with plants. In many cases little beyond worry and anxiety have resulted from the arrangements. A garden was once offered to me almost at my own terms, but I declined it. There was a time, or say up to about fifteen years ago, when fruit and vegetables sold well. Grapes, Peaches, Strawberries, Melons, Cucumbers, and hardy fruits generally all realised highly remunerative prices, and the same might be said of vegetables, forced or otherwise. All this is now altered. The case with cut flowers is different. These, although largely imported, are of a more perishable nature, and the home grower can more than hold his own with the foreigner during the greater part of the year. Unfortunately very few of the glass structures in private gardens are well adapted for the cultivation of flowering plants, added to which one of the conditions imposed on gardeners renting private places is that everything at the end of a fixed lease shall be left exactly in the same state as the lessee takes it over. This, for obvious reasons, is fatal to ultimate success.

Instead of the gardener renting a garden, let him propose that he do the best he can with everything, both as regards economising labour and marketing produce; and let him have, as I have, 10 per

cent. commission on all the sales of garden produce effected, the home consumption being exempted. This is best for the master and fair to the man. Growing for sale, including the all-important details of finding the best markets, packing and booking, entails very much extra labour and worry for the gardener, but if he has a direct interest in the success of the undertaking he will never slacken in his attention to the work, but, on the contrary, there is every probability of the owner of the garden being a great gainer rather than a loser by the bonus given. The sum (2s. in the pound) is not one penny too much, and ought to be unstintingly granted to every private gardener who markets surplus produce, no matter in how small quantities.

I propose to treat on flowers that I have found can be profitably cultivated, giving the requisite details. It will be found that the most prominence will be given to plants producing white flowers, the demand for these being far in excess of coloured flowers generally, though there a few of the latter that pay well. What I have found the most profitable are Tea Roses, including the very popular Maréchal Niel, Eucharises, Pancratiums, Chrysanthemums, Christmas Roses, Bouvardias, double white Primulas, Richardias, Violets, Cyclamens, Stephanotis, Carnations, Spiræas, and in a lesser degree Lilies of the Valley, Roman Hyacinths, Tuberoses, Camellias, Azaleas, Double Zonal Pelargoniums, white Begonias, Clivias, Allamandas, Gardenias, Poinsettias, Adiantums, Liliun candidum, Mignonette, and a few Orchids.—M. H.

NOTES ON FORCING VEGETABLES.

FRENCH OR KIDNEY BEANS.

THE Kidney Bean, being a native of India, is only had in perfection with us in the warmer months of summer. It cannot be ventured in the open air till all chance of spring frosts is over, and it is sometimes cut down very early in the autumn just when perfecting its crop. Especially was this the case with us in 1888, when the plants were killed by frost on October 1st. It is a vegetable that is much esteemed, and cannot be had too early; but it is not so easy to force as some others. For early forcing it requires a high temperature—viz., from 60° to 70°, never falling below 60°. It is very liable to be attacked by red spider, and a constant use of the syringe must be maintained. They must never be allowed to suffer through having insufficient water at the roots, or red spider is sure to appear. If this pest attack the plants they should be well syringed with water mixed with sulphur and soft-soap—2 ozs. of the latter and 1 oz. of sulphur to a gallon of water, the plants being laid on their sides while syringing them.

For early forcing the plants should be grown in 8 or 9-inch pots. Some growers raise these Beans in 60-sized pots, and after they are well up shift them into the size just named. But I prefer placing them in their largest pots at once for two reasons—viz., it saves time; and when they are raised in 3-inch pots, if they are not repotted as soon as the roots touch the sides, they soon become root-bound, and they receive a check from which they do not quickly recover. Some leave room for a top-dressing; but this is not necessary, as they will do quite as well without.

The soil should not be too strong, a compost of equal parts of leaf mould and loam, with plenty of sand and a sprinkling of charcoal dust, suits them well. A little of Thomson's, or any approved artificial manure, given when the plants are fruiting and watered in, will help to lengthen the fruiting period. As the spring months advance Kidney Beans may be grown in Melon houses and heated pits or frames, with or without bottom heat. Of course if bottom heat can be had so much the better. We plant in our Melon houses at the beginning of February, raising the Beans in boxes on hot-water pipes, but they may also be raised in 3-inch pots and planted out. As the Beans advance in growth they should be supported by twigs or sticks. Sow some at intervals to keep up the supply. As pits or frames are cleared of early Potatoes they may be filled with Kidney Beans, and thus the supply can be kept up till they can be gathered from outdoor plants. The best sorts for forcing are Osborn's Prolific and Ne Plus Ultra.

RHUBARB.

Rhubarb is found to be much improved in flavour by being blanched, as well as effecting a saving of sugar in rendering it agreeable to the palate when served. According to the doctrine of Knight, Rhubarb, like most other perennial herbaceous plants, contains within itself during winter all the organisable matter which it expends in the formation of its flowerstalks and leaves, and requires neither food nor light to enable it to produce either. All it requires are heat and moisture. The roots of Rhubarb dug up entire at any period after the decay of the leaves of the preceding season, and taken into a forcing house, there placed upon the surface of the borders in a convenient place and supplied with

plenty of water, will produce a reasonable quantity of leafstalks for use during the winter months.

Those who have a Mushroom house will find it a very convenient place for forcing Rhubarb. By putting a few roots in (according to the demand) about once a month a supply will be forthcoming all the winter. Another excellent way to force it after the month of February (where plenty of stable manure can be had) is to prepare manure or manure and leaves the same as for a hotbed, and wheel it on the beds where the Rhubarb is growing, first covering the stools with forcing pots or anything that can be had to keep the manure a sufficient distance away to permit the leafstalks being thrown up freely. The manure should be placed on and round the pots to the depth of a foot or 18 inches, so as to prolong a gentle heat, and in a short time plenty of Rhubarb will be fit for pulling, and will continue to be thrown up till it can be had without artificial means.

SEAKALE.

Few vegetables are improved more by cultivation than Seakale, and few are more useful for forcing. Like the Rhubarb it is easily managed, and can be forced in a variety of ways. I have forced it in champagne cases on the top of a saddle boiler. The roots were placed closely in one case among soil and another case placed on the top to insure the growth being blanched. Very good Kale was thus produced, which gave much satisfaction. It can also be grown in 16-sized pots, with an inverted pot the same size over it, placed in a forcing house under a stage or in any convenient place where a temperature can be maintained at from 50° to 60°. It also does very well in the Mushroom house in company with the Rhubarb placed near to the hot-water pipes, taking care that it has sufficient water. If roots (the quantity according to the demand) are placed in at intervals of two or three weeks a constant supply will be had through the winter months. Seakale roots should be dug up about the end of October and placed in ashes in an open shed or some convenient place in readiness for taking to the forcing house as required.—G. HILTON.

INSECTS OF THE FLOWER GARDEN.

(Continued from page 375.)

A LARGE family of small moths is that sometimes familiarly called that of the bell moths, because when we see them at rest upon palings they assume the bell shape. Often do we notice them flying in little parties during the twilight of summer or autumn, though some take their excursions in the brightness of noon. Also we name them the Tortricidæ, which we may render "the twisters," derived from the habits of the caterpillars, as they twist or bend the leaves and shoots of their food plants to afford themselves shelter from their foes and the weather. Most of them choose for their food the leaves of trees and a variety of wild shrubs; only a few of them trouble us in the flower garden. Certain species of the family are unfortunately too well known as enemies to our fruit trees, and their particular mode of life renders it difficult to deal with them effectively, and yet avoid all damage to the tree or plant upon which they feed. To only a small number of these and their lesser brethren, the Tineidæ, have English names been attached; these are not usually appropriate, sometimes even ridiculous.

There is a silvery grey, narrow-winged moth, expanding about an inch, and very active, which is so frequently to be seen in our gardens during the summer, and is named *Pylalis glaucinalis*. It would be a natural conclusion that it fed, as caterpillar, upon some garden plant, but it is not so, as the Nettle affords it nutriment, a plant which has no business to be in any garden as a resident. A late-feeding caterpillar, noticeable in September and October, which produces the moth called *Ebulea sambucalis*, occurs upon garden Convolvuluses; sometimes drawing the leaves together, its proceedings are not very observable at first. It is pale green, lined with white or pink, and if alarmed, drops suddenly from the plant. The Honeysuckle is a plant much infested some seasons with caterpillars, as also with aphides. When it should be full of flower, the shoots and leaves may be contorted in May and June by the caterpillar of *Tortrix xylostæana*, a pretty little creature, of a dull olive green, having whitish spots with black centres. By judiciously shaking the shoots the caterpillars may be made to fall from their retreats, each hanging by a thread, and can thus be captured. The moth flies in July. Another foe to the Honeysuckle feeds on the leaves later, about August, this is *Grapholita albersana*. It is a greenish grey colour, with a yellow head, large for the body, and a shield or plate behind it, black dots are placed from head to tail in pairs. In feeding this caterpillar selects two full-sized leaves, and binds them together with silk, then remains hidden until it has eaten the upper surfaces, when it migrates. We see the moth

flitting in the twilight of May, the small brown wings are marked with white and gold. Then the variable *G. hypericana*, brownish also, but paler, and streaked with black and gold, comes from a green or greyish caterpillar, which feeds upon the flower-heads or tops of St. John's Worts, or garden plants allied to the Hypericums.

Our queen of flowers, the Rose, is singled out for attack by more than one species of Tortrix, and it needs a watchful eye to detect the eggs, which are frequently deposited on the stems in autumn, to be hatched out in the spring. It is often the case that during April and May, when the caterpillars are feeding, they have both weakened and disfigured the Roses before the gardener is awake to the mischief. *T. Bergmanniana* is very troublesome in the south of England, but is scarcer in the north. Most gardeners have seen the little caterpillar of a pale green, with a shining jet black head, wriggling from a doubled-up leaf, and small as it is its appetite is considerable. First it damages the buds, checking their expansion, then feasts on the leaves. We find the moth flying by day at the end of June and in July; under a hand magnifier it is seen to have lustrous markings of violet upon the lemon ground colour. Then the caterpillar of *Spilonota roborana* feeds about the same time. This is also black-headed, but the body of a dull brown colour. It has a penchant unfortunately for the tops of young shoots, which it doubles up in a fashion that checks their development. A third caterpillar infesting the Rose is *S. ocellana*, allied to the former but less common. The moths in both are very variable in appearance. Probably careful hand-picking is the best remedy for all these. Of course syringing will remove some of them, and dusting the leaves with sulphur while they are damp has been recommended.

A small moth, with glossy, pale brown wings, common in many places, named *Anchylopera lundana*, is developed from a grey caterpillar spotted with black, and having a pale shield behind the head. The usual food is some leguminous plant, of which it unites the leaves, such as *Vicia* or *Lathyrus*. There appear to be two broods yearly. Though named from the Rose, the caterpillar of *Eupæcilia roseana* conceals itself in the heads of composite plants in gardens, devouring the immature seeds about August or September. It is yellowish white, and adorned with some raised spots; down the back runs a white line. Another enemy of the composites is the caterpillar of *Halonota fænella*. The mature insect is remarkable for having upon the dark brown wings a curved white mark, resembling the head and neck of a bird. While quite young its caterpillar bores into the stem of a plant 3 or 4 inches from the ground, and works down to the roots, where it may be seen early in the year, becoming a pupa about May. It is yellowish white, has a brown shield, and a heart-shaped shining head. The plants attacked seldom survive the injury.

In the group of moths called the Vineæ are many species which, when in the caterpillar state, by feeding upon buds, leaves, or flowers somewhat disfigure them, and a few are specially destructive to trees, however, rather than to the plants of our beds and borders. A species called the greystreak (*Plutella porrectella*) is tolerably familiar to gardeners, since it attacks persistently the Rocket, and several other garden plants in the same family. The moths, which are greyish white, except some spots of black and brown, seem to occur in colonies. A brood is noticeable in early summer, and another about two months later, so that there are also two broods of the caterpillar; of these the first does the more mischief, as it feeds upon plants while the leaves are tender. A bunch of the terminal leaves are, by means of a silken cord, tied together, and within this shelter the caterpillar lives securely, at least from bird and insect foes. Occasionally we discover a party of three or five have joined company, and formed for themselves a general covering. It is surprising how these, and similarly small caterpillars, can manage to pull or twist the leaves and stems of plants, even when working solitarily. These caterpillars may be destroyed by throwing tobacco water or a decoction of quassia over the plants. In the genus *Depressaria*, where the moths have flat, elongated bodies, several of the caterpillars are sometimes found feeding upon the flower heads of the umbelliferous species cultivated in gardens, or such species as the *Centaurea*; their webs are noticeable, and should be promptly removed. To this group belongs the one called the confluent barred moth (*Gracillaria syringella*), a pretty species of yellow, black, and brown, but very injurious to the Lilac. It appears to attack this shrub most persistently when it is growing in or near a town. I seldom find Lilacs in the country much troubled by it. Near London the Lilacs are nearly defoliated by it in some seasons, as there is both a spring and an autumn brood of the caterpillars. They commence proceedings by mining the leaves, causing blotches; when they get larger they roll the leaves, and so effectually as to defy all enemies. Many may be, however, shaken from these retreats and then destroyed. Young Lilacs are, in some instances, greatly

retarded in their growth by the insect, and older shrubs are weakened, the result being that they exhibit few flowers.—
ENTOMOLOGIST.

FORCING SHRUBS.

THE forcing of hardy shrubs is not carried out with so much alacrity in these times as in my younger days. I well remember that forty or fifty years since this hardy shrub forcing was one of the most important affairs for consideration in the month of November. And why? Simply because they had scarcely any flowers in those days which blossomed naturally in winter; but, as is now the case with the natives of Britain, the love of flowers did not cease even in the dormant season. There was still a hankering after them in defiance of snow storms and the ravages of King Frost—that imperious monarch who attempts to bind in fetters the pets of the vegetable kingdom.

In those days to which I have adverted gardeners used to rush into the nurseries about the metropolis at the beginning of November to mark American shrubs for forcing, and to select Moss and Cabbage Roses for forcing purposes, and some other little things, in order to sustain a kind of plant house through the winter; and although a little wide of my purpose, I may observe that there was a great demand for Asparagus roots and Seakale, in order to keep the cook in temper.

But we have had such a splendid lot of plants introduced during the last score years that flower naturally or with little excitement through the winter that we care much less about this shrub forcing; and indeed it is well so, for no man can force these hardy shrubs well at an early period without something like a special provision for them. But as there are those who still love to indulge in a forced Moss or Cabbage Rose, a hardy or American Azalea, &c., I will make bold to proceed with my remarks. And first let me point to the names of a few of the families which stand foremost in this affair. I must place them in the order in which they occur to me.

Roses Moss and Provence, Azaleas the American, Lilacs, Mezereon, Honeysuckle, Sweet Briar, Ribes sanguineum, Deutzias, Weigelas, Forsythias, Sedums, Andromedas, Rhododendrons, Kalmias, and Rhodoras. These are a few of what used to constitute forcing materials as to mere shrubs, and let me add that they still possess much interest.

Now in the first place, unless these shrubs have made a growth adapted to forcing purposes previously, it is in vain to expect a high degree of success. In order to render the matter familiar to readers who do not understand the formation of blossom buds in plants I will put a case or two. Most are familiar with our hardy American Azaleas. They have seen bunches of these with blossom buds on some points and none on others. This must strike any ordinary observer. Now the barrenness of some shoots may arise from more than one or two causes. In the first place those shoots may be too luxuriant, or they may be late growths, or they may have been too much shaded by other growths, or, finally, they may have been too weak to produce a blossom bud, for a certain amount of strength is indispensable, although too much constitutes in many plants an invincible coarseness. The conditions requisite to form blossom buds in this family are an intermediate strength of wood, early growth, and ripening the wood.

And now I may allude to the Moss Rose, and this is more difficult, I confess, to explain. It does not blossom from the terminal points of the old wood like the Azalea, but from small buds like pin-heads, with which the sides of such shoots are studded. As to why it should be so I cannot fully explain, for it does appear strange in pruning such Roses to cut back to these simple-looking affairs; but this may suffice to point to the great difference in habit between such things as the Azalea and the Rose.

In looking over the plants suggested for forcing purposes I perceive it necessary to observe that some of them must be established in pots to succeed, and that others are quite as well removed from the open ground. Roses are almost useless unless well established in pots. Lilacs have ever been thought best thus established; Sweet Briars the same, and let us add the Mezereon; but when we come to the American plants the case somewhat differs. These have been taken from the open ground, and forced immediately for probably nearly a century.

As to the conditions requisite for forcing them, for, although they will blossom in due time stuck on a greenhouse shelf, yet to have them flower at the end of January, or sooner, requires a special course of treatment. A moist heat is of the highest importance; but that genial moisture which is destined to qualify the heat used, and to satisfy gaping pores in the foliage, depends but too often on the chances at command rather than on principle. After all, gardeners seem to admit that there is nothing like a dung bed, and, indeed, there is much truth in the opinion; but we must in the

main try to do with such means as lay at our elbows. Be such what they may, a certain amount of heat and also of air moisture is absolutely essential in order to command success. Bottom heat, too, is of great importance in this matter. All shrubs force much better for plunging in a proper medium. Not that they will not succeed without it. They should by all means have as light a situation as possible, and be near to the glass.

With regard to air heat it may be very moderate during the first stage of forcing, for our business is to excite a root action first, and, indeed, under any circumstances the buds of these plants require a given time to develop themselves.

Speaking here of the development of blossom buds reminds me of the length of time the Camellia requires to swell and expand the blossom bud. The latter, first manifest in May or June, cannot by fair means be made to expand before November. Here we see half a year consumed in organising and expanding the bud. This is, however, no great marvel when we consider the great amount of well-constructed petals which a bud contains, and which must of necessity take much time in perfecting, so that the beginner in forcing matters must not be astonished and impatient that his things make such slow advances. But it is so in all forcing matters. The Vine, Peach, and Strawberry all have to swell and expand their buds in a tardy way. As for Strawberries, one of the chief secrets of their successful forcing is to bring them forward in their earlier stages by a low temperature and by almost imperceptible degrees.

But to return to our shrubs for forcing. Let me observe that those which are deciduous, as the Moss Rose, Rhodoras, American Azaleas, and Lilacs will pass the first three weeks of their forcing with very little light if needs be. They have little occasion for light until the foliage commences development. The knowledge of this fact may sometimes enable the operator to economise his space.

During the time that the bud is expanding syringing should be used both morning and evening, providing there is fire heat applied to the structure. If only dung heat, and the weather is dull, the syringe must certainly be dispensed with, as the steam from the fermenting materials will be amply sufficient. A liberal ventilation is proper. These hardy things cannot bear coddling, and in order to carry out such it is necessary to be provided with plenty of heat to meet such contingencies. Where persons force with the aid of fire heat in combination with bottom heat this is easily accomplished. Where dung pits are used without fire it is very difficult, and the consequence is that much putrefaction through damp is engendered through the earliest part of the spring. Of course watering at the root must be attended to, and it may be observed that American plants taken up with balls of earth require very liberal waterings, especially as they approach the blossoming state.

Here I may as well advert to the potting them from the open soil. I before observed that there would be what is termed "a ball"—that is to say, a mass of fibres, from which the soil is with difficulty disengaged. Now, this ball is not by any means so readily permeable by water as the loose soil by which it is surrounded in the act of potting, therefore in the act of potting caution should be exercised, and the soil should be pressed in very firmly around the ball; but, be it remembered, that soils in a moist state will not bear much pressure, therefore it becomes necessary to use dryish soil.

I may here speak of retarding matters, and have to observe that this class of flowers are in general so susceptible of extremes of temperature in the heat way that, unless caution is exercised, their beauties are soon dissipated. Azaleas and Rhododendrons left in a hot place where the forcing is carried on will not endure above a fortnight in all their freshness. Removed to a cool house or room they will in most cases endure treble the time, especially if kept from much sunshine. Plants of this description are the better for a little pruning previously to their being introduced to heat. Lilacs and Azaleas often possess a few coarse shoots projecting beyond the true blossom. These having no blossom buds on are simply in the way of the object sought, and may be pruned close back.—E. N.

THE LATE CLYDE DISASTER.

At the final meeting of the Committee, held at the offices of Messrs. Protheroe & Morris on the 20th of December, Mr. H. J. Veitch presiding, Mr. Horsman, the Honorary Secretary, announced that the total receipts amounted to £453 3s., and it was unanimously

resolved—first, that the subscription list be declared closed; second, that the sum of £452 be equally divided between Mrs. Hall and Mrs. Fraser; third, that the arrangements for investing the respective amounts be left in the hands of Mr. Veitch and Mr. Protheroe; and fourth, that as soon as the investments have been made a report be sent to all subscribers. Mr. Horsman was accorded a hearty vote of thanks for his services as Secretary, as also were the editors of the various gardening papers for their kind co-operation in giving publicity to the Committee's proceedings.

CYPRIPEDIUM GALATEA MAJUS.

HYBRID *Cypripediums* are so numerous that it might now be thought difficult to obtain distinct and meritorious novelties, but this does not appear to be the case, and additions are constantly being made to the lists of handsome seedlings. During the next four years we may expect to see many more, for some thousands of seedlings have been raised, both by amateurs and nurserymen.

Cypripedium Galatea majus was exhibited by Baron Schröder

FIG. 1.—CYPRIPEDIUM GALATEA MAJUS.

at the last meeting of the Royal Horticultural Society in the Drill Hall, Westminster, when an award of merit was granted for it. The plant is a seedling which resulted from a cross between *Cypripedium Chantini* and *C. Harrisianum*, and the flowers have a fine bold appearance, quite distinct and beautiful. The dorsal sepal is edged with pure white, the centre heavily spotted with deep crimson; the lower sepals pale green, with a few spots. The petals are purple tinted, tipped with green, and the lip is of moderate size, with a polished shining surface, and of a purplish colour.—L. C.

ORCHIDS IN FLOWER.

MESSRS. B. S. WILLIAMS & SON, Upper Holloway, have the following Orchids in flower at the present time, and for mid-winter it is a surprising display:—*Calanthes bella*, *Masuca*, *Mylesi*, *Sandhurstiana*, *Sedeni*, *Veitchi*, and *vestita luteo-oculata*, *vestita rubro-oculata*; *Cattleya Walkeriana*, *Cœlogynes barbata* and *speciosa*, *Compæretia macroplectron*, *Cypripediums Amesianum*, *Ashburtoniæ*, *barbatum biflorum*, *callosum*, *calophyllum*, *calurum*, *cardinale*, *chloroneurum*, *conchiferum*, *concolor*, *Dauthieri marmoratum*,

Fitchianum, Harrisianum, Harrisianum vivicans, Haynaldianum, insigne, insigne albo-marginatum, insigne aureum, insigne Foster-manni, insigne Mrs. Wilson, insigne Mooreanum, insigne punctatum violaceum, Lceanum, Lceanum superbum, Measuresianum, Meirax (C. oenanthum superbum), nitens, nitens superbum, politum, Sallieri, Sallieri aureum, Schlimi, Sedeni, Sedeni candidulum, Sedeni superbum, Spicerianum, Swanianum, and Williamsianum; Dendrobiums bigibbum, Fytchianum roseum, Linawianum, and superbians; Epidendrum cuspidatum, Lælias autumnalis and Gouldiana, Limatodes rosea, Lycastes plana alba (L. fulvescens), Skinneri, Skinneri amabilis and alba; Masdevallias amabilis, chimera Back-houseana, polysticta, and tovarensis; Miltonia Russelliana, Odontoglossums Alexandræ, angustatum, aspersum, constrictum, gloriosum, Horsmanni, Harryanum, purum, and Rossi majus (O. roseum); Oncidiums bracteatum, Forbesi, macranthum, obryzatum, prætextum, and tigrinum; Sophronitis grandiflora, Trichosma suavis, Vandas Amesiana (very large flowers), suavis, tricolor, tricolor formosa, and tricolor superba; Warscewiczella discolor.

CELOGYNE CRISTATA.

A DESERVEDLY popular favourite, and it might well be often grown in quantity. A plant or two are grown in the majority of gardens where fifty would not be too many. The price is certainly not high, though large and well grown specimens will fetch good value. There are several varieties of the type. For instance, we have Chatsworth, Trentham, Lemoniana, and maxima varieties besides the ordinary cristata. Of course the latter is the cheapest, but where possible they should all be grown, as they prolong the season. Maxima is a noble variety, and in a few years' time when the small plants now in gardens grow into fair-sized specimens they will have a grand effect. In many gardens they are grown in too cool a temperature. They will certainly grow in a cool Orchid house, but they thrive far better in an intermediate house, and this is the temperature they must be grown in if pseudo-bulbs are expected the size of fowls' eggs, with several flowers to a spike. Our plants are now showing flower spikes abundantly, and are kept dry, as if too moist the spikes are apt to damp. Sufficient water must be supplied to keep the pseudo-bulbs from shrinking. As the spikes advance more water must be applied, and after flowering again keep them dry until the new growths appear. Water may now be more freely applied, and as the long days appear water must be given abundantly, watering overhead twice a day. Keep the plants near to the glass, but shade from strong sun. Towards the autumn, say at the commencement of September, they will be benefited by a little more heat to finish their growths and swell out the pseudo-bulbs. All this time we place our Cœlogynes in a plant stove, in which position they finish well. Once in two or three years is often enough to repot the plants, but if the compost should be sour repot at any time. Cœlogynes do not like to be disturbed too much, but they should not be allowed to suffer from the want of root space.

SOPHRONITIS GRANDIFLORA.

A little gem for winter flowering, and we have several specimens with from six to twelve flowers each. They are useful for buttonholes at Christmas time. These I think are grown too cool as a rule. Our plants are in the cool Orchid house during the spring and summer months, but during the autumn and winter are placed in an intermediate house along with the Cœlogynes. In this position the flowers come larger, and are also of better colour. The plants should be grown in small baskets or shallow pans. Ample drainage must be provided, and the compost should consist of two parts of fibrous peat and one part sphagnum, with small pieces of charcoal. Very little of this is necessary, but what there is must be pressed firmly in the pans.

PHAIUS GRANDIFOLIUS.

In the interesting notes on Aldin Grange Gardens, Mr. Lewis Castle mentions what fine results Mr. Jenkins has had with this interesting old plant, and I can fully endorse what he there says. I fancy there must be a revival setting in, as until lately this plant has been rarely mentioned. It is a great favourite of mine, and last season we had it very fine, when it was greatly admired by the ladies. We have specimens now with a dozen spikes throwing up vigorously. When in bloom it may be placed in the conservatory, and may also be placed in the house without any ill effects.

WINTER-FLOWERING CALANTHES.

These are now in full beauty, and well they repay the trouble bestowed on them. We have had between 300 and 400 spikes from 3 feet to 4 feet in length, and most useful we find them, especially for the decoration of the dinner table, when they have a telling effect. The culture has been given lately by various correspondents, so probably it will not be necessary to refer to it here. But there

is one point which I cannot understand which some cultivators dwell on, and that is to water until the spikes are fully expanded. Now, according to my experience, this is bad practice. Our plan is to reduce the supply when the spikes are 10 inches or so in length, and by the time the first flowers open to stop altogether. For four seasons we have followed this practice with larger pseudo-bulbs; and consequently longer spikes following. This does not look like degenerating.—A. YOUNG.

CYPRIPEDIUM INSIGNE.

PLANTS that were assisted to make their growth early in the year are now past their best, and are being removed from the conservatory. Their places are being taken by plants that have been grown cool until the flower spikes were visible, when they were aided by gentle heat. These do not flower so profusely or carry such fine blooms as those assisted by heat to make their growth early in the year. Cypripediums that have flowered should be kept cool or in a similar temperature to that maintained in the conservatory until near the end of next month, when they may be started into growth in a vinery or any structure where the temperature to commence with will not fall below 50°. If started at once the plants finish their growth too early, and the flowers appear at a season when they are not really wanted. The plants may be examined, and what top-dressing is needed may be done as they are started into growth. Repotting will not be requisite until the roots have commenced activity.

CYPRIPEDIUM VENUSTUM.

Although the flowers are less conspicuous than those of C. insigne, this plant is useful for the conservatory at this season, or to follow C. insigne. The dark foliage is very ornamental amongst other flowering plants. Large pans well flowered look well where suitable positions can be found for them. Pans of this plant in flower are stiff, and if care is not used they destroy tasteful arrangements. We invariably arrange large pans near the end of low stages and elevate them on 6 or 8-inch pots, and then surround the pan with small Ferns—just to hide the pan—from amongst these, small plants of Odontoglossum Alexandræ look well. If these are not to hand a few Duc Van Thol Tulips; a few sprays of Lily of the Valley in small pots are not out of place.

CYPRIPEDIUM VILLOSUM.

This is one of the best for conservatory decoration, and follows capitally the two that have been named. The flowers are just visible, and the plants can be retarded or pushed forward according to requirements. Hitherto we have found that this variety is most useful in flower about the end of January, and in structures where the temperature ranges 45° to 50° the flowers last fresh for nearly three months.—ORCHID GROWER.

THE GARDENERS' ORPHAN FUND.

THE last meeting of the Committee for 1889 took place at the Caledonian Hotel, Adelphi, W.C., Mr. George Deal in the chair. The minutes of the last meeting having been read and signed, the following sums, among others, were announced as having been received during the past month:—From Mr. G. W. Cummins, The Grange Gardens, Wallington, Show of Chrysanthemums, box £1 19s.; Croydon Chrysanthemum Society, £1 1s.; Isle of Thanet Chrysanthemum Society, per Mr. Millar, local Secretary, 13s. 2d.; Mr. Chapman, gardener to H. W. Robinson, Esq., Romford, Show of Chrysanthemums, box, 13s.; Mr. C. Gibson, Morden Park Gardens, Mitcham Chrysanthemum Society, 9s.; Mr. Searing, Sevenoaks, donation from Gardeners' Mutual Improvement Society, £1; from Mr. Henry Deverill, seedsman, Banbury, box in office, £3; Mr. R. Scott, Broadfield, Yorkshire, Show of Chrysanthemums, £4 0s. 2d.; young gardeners, The Grove, Stanmore, fees to botany class conducted by Mr. J. Odell, who gave his services gratuitously, £3; Ancient Society of York Florists, proceeds of a floral service at one of the churches, and sale of flowers at Chrysanthemum Show, per Mr. J. Lazenby, £10; Ealing Gardeners' Mutual Improvement Society, proceeds of concert, per Mr. C. Chadwick, Secretary, £20 2s., with the request this sum should be divided into four portions of £5, and life subscribers' votes given to Messrs. E. Chadwick, G. Cannon, E. Fountain, and A. Wright. A letter was read from Mr. W. Richards in reply to the letter of condolence sent to him by the members of the Committee at their last meeting, expressing his grateful thanks for their expressions of good-will and sympathy. A letter was read from Mr. Gleeson, Clumber Gardens, announcing that in addition to a few private subscriptions, the amount realised at the recent concert at Worksop, and stating the intention of the promoters to make the sum up to £60, and place a child from that neighbourhood upon the Fund for the space of six years, under the terms of the rule permitting that privilege. Mr. J. Brown, The Gardens, Great Doods, Reigate, wrote that the Reigate and District Chrysanthemum Society having made a profit of £100, had resolved to present £50 each to the Gardeners' Orphan Fund and the Gardeners' Royal Benevolent Institution. The Hon. Secretary, Mr. A. F. Barron, announced that the Fund had been granted a benefit

performance at the Theatre Royal, Covent Garden, and tickets could be had-admitting the holder to a morning or evening performance on any day between the 3rd and 14th of February inclusive. A cheque was drawn for the quarter's allowances to the children enjoying the benefit of the Fund, amounting to £61 15s. A vote of thanks to the Chairman closed the proceedings.

A REVIEW OF THE PAST SEASON.

TAKEN as a whole the past season must be classed as one of the best of recent years. When we consider the number of exhibitions that have been held in such a short space of time it indicates how the interest is increasing in the cultivation of this popular flower, and we hear of increased financial successes, a sign that the public appreciate the efforts of societies and exhibitors.

I do not remember a season for the last ten years where there was so much keen competition for the prizes offered in various parts of the country. During the latter part of the season, say from the 12th of November until the end, it cannot be said that the incurved blooms staged were quite up to that high standard of excellence which we would like to see. There are two reasons to which I attribute this defect. In the first place, and perhaps it is the more serious of the two, the great loss of fine blooms, notably in the Queen family, through an early flowering season, and by what is known and feared amongst growers as "damping." Unfortunately, many cultivators were so situated that the late date of some important exhibitions was quite unsuited for the stage of their flowers, which was unavoidable after it was known that an early season was likely to ensue. I know of several northern exhibitors who were quite out of the running by the early season and late dates of the exhibitions, who would otherwise have been strong had the shows been held but one week earlier. Under those circumstances such growers were placed at a disadvantage. At the same time this cannot be advanced as an excuse for non-success. More credit certainly is due to the cultivator who timed his plants in such a manner that he was enabled to hold his own in competitions where he entered. I have thought for the last two or three years that northern societies fixed the dates of their exhibitions one week too late, and I am more than ever convinced of this after the present year's experience. In this I am speaking with the concurrence of officials of some northern shows. I know that circumstances work against wishes in some instances, such as being unable to obtain the regular place of exhibition at given dates; but where such difficulty does not exist I think societies would gain by trying a date one week earlier. So often do we hear the remark from exhibitors, "If it had only been last week, I had such blooms of so-and-so (quoting their names); but, alas! they are gone." Every year the seasons seem to be earlier and earlier, that a few years since to talk of an exhibition in October would have been considered absurd, but now capital ones are held during that month. Indeed, at the first show I attended this year there were blooms of some sorts better than I have seen all the season through.

The second reason which I consider caused a defect in the stands of incurved blooms is that owing to there being so many shows at about the same date sufficient time is not given to the preparation of the blooms requisite to present them in the best condition. Exhibitors are naturally anxious to secure as many honours as possible in a short space, but I think many will agree with me that the blooms suffer somewhat on this account. In conversation with a first prize winner at a large northern exhibition I said, "If your blooms were a little better finished they would be improved." The answer was, "We had not time to spend with them properly. There was another stand of blooms to be prepared for so-and-so, and we could not do it."

The blooms in the incurved section at the northern shows did not present such neatness and finish as those staged at the southern shows, which, owing to being so much earlier, gave the southern exhibitors an advantage in point of freshness of considerable value in the case of incurved blooms. Blooms, although large, yet rough in character, many with defective centres, do not present that pleasing appearance and quality as do medium-sized, better formed, and consequently smoother specimens; it is these latter which find most favour both with the public and judges alike. At the early shows the incurved gave great promise, but the sudden attack of damping which made itself felt after November 8th prevented the early promise of an exceptionally good season being fulfilled.

The Japanese section did not suffer in the same proportion through the same cause. They have been well shown all through the season, being large, well coloured, and generally well staged. In some few instances the reverse has been the case. The blooms have been placed much too low on the stands, which is a great mistake; the blooms lose so much in appearance, as they do not then exhibit their full size or form. Such standard varieties as *Boule d'Or*, *Avalanche*, *Ralph Brocklebank*, *Criterion*, *Jeanne Delaux*, and *Mdme. Laing* have maintained their position. *Edwin Molyneux* and *Mdme. C. Audiguier* have been

seen in nearly all the leading stands, though perhaps of not quite such good quality. The slight falling off in the case of the former I attribute mainly to the early season and the late dates of the shows.

During the early part of the season the "Queens" were shown in capital condition, being large, well built, good in colour, and neatly staged, but later on, owing to the prevalence of damp, which causes serious injury to the florets, especially the lower part of the flowers, they were somewhat rough and in some instances very stale on the exhibition table. *Princess of Wales* and its sports, especially the newer ones, have come out remarkably well, maintaining their position as flowers of the first order of merit. *Anemone* flowers, especially the large show section, have been well and numerously staged, not that large size has been the main point; the fullness of the centre or disc, the chief point in *Anemone* flowers, has been remarkably well developed. The same praise cannot be bestowed on the Japanese *Anemone* section, the majority of the blooms exhibited lacked what the show kinds predominated in—full centres. A poor object indeed is a Japanese *Anemone* bloom with little or no centre, the thinness of the ray florets in some cases seems to aggravate the appearance of thin-centred flowers. The one variety above all others which three or four years since was looked upon as being the ideal Japanese *Anemone*, is now the most defective in this respect; I allude to *Fabian de Mediana*. Can it be possible that the constitution of this variety in wearing out, the stock needing a rest and a restitution of its strength by planting out in the open for a season or two? Perhaps this is the reason why so many badly coloured blooms are nowadays to be seen. With a few exceptions the blooms belonging to the reflexed section have not been exhibited in quite such good form as they were two or three years since. Although they have been even in size, fairly good in quality, they have not been well developed, thus lacking size and depth of petal, the latter a great point in a reflexed flower. One improvement in the staging of this section I am pleased to see is the gradual withdrawal of varieties which cannot be strictly classed as reflexed flowers of the correct type; for instance, *Magdeleine Tezier*, *Garibaldi*, and the like, which have a habit of incurving the tips of their florets instead of imbricating them, as in the case of such true examples as *Cloth of Gold* and *King of Crimson*.

In the north of England and Scotland, too, it is surprising what little interest is taken amongst cultivators in these three last mentioned sections. The incurved and Japanese families appear to absorb nearly their whole attention, although I noticed an improvement in the reflexed and show *Anemone* classes at Liverpool as compared with last year even. At York and Edinburgh they were especially poorly represented. I presume it is merely a want of interest in these sections on the part of the growers which prevents their being seen in better condition. Perhaps I ought to except Hull in my complaint, as there were at that Show one or two good stands of *Anemone* blooms, the winner in this class being noted for this section, which points more strongly than ever to the fact of want of interest being the true cause of defective blooms.

Pompons or *Pompon Anemone* varieties receive but scant attention in the north, which is a pity, as they add variety to an exhibition. Even the first prize stand at Hull fell short of what is to be seen at metropolitan exhibitions, not that I regard size as the standpoint of quality in a *Pompon*, I look upon form characteristic of the variety, avoiding all advances to coarseness, as in that manner I think the true *Pompon* is spoilt; full, close petalled blooms are what I like to see, which was the case of many of those in the stand in question. The only fault I could find in that was a lack of evenness. I did not see a stand of blooms worthy of the name, nearly all were badly staged, being cut with much too short a stem to each, rendering them short of foliage, which is just what is needed to give them a good appearance. In some cases they were placed in threes hard down on the stands, which gave the blooms a cramped appearance. There appears to be a lack of variety also, of which there is no necessity, as there is abundance of material in that direction. It is only the want of interest to be more keenly displayed I am sure, and then we should see these classes as well represented in the north of England as they are in the south.

It will be seen that my whole remarks apply to the cut blooms simply for the reason that a much greater interest is taken in this part of *Chrysanthemum* culture than any other, the remainder I hope to discuss in another issue.

DATES OF SHOWS.

I notice that there is an evident disposition amongst societies to lose no time in fixing the dates of their exhibitions for 1890. I am pleased to see this, as it shows a wish to avoid clashing with each other where such clashing of dates would interfere with the success of those concerned. It does seem a pity that societies, or their responsible officials, should not endeavour to steer clear of each other wherever it may be practicable. I am well aware that circumstances leave little choice sometimes, such as the inability to secure their recognised place of exhibition for a desired date. I note that the two most important societies in and near London, the National and Kingston, are both fixed for the same dates. As far as I have been able to judge during the last half dozen years it matters little whether the dates be the same or not, because both Societies have ample supporters for insuring fine exhibitions. Societies have their own affairs to consider, independently of others, but where arrangements can be made amicably with each other it is well such should be done. Where the dates can be given

thus early, it allows others the means of arranging their dates in accordance. Portsmouth has chosen November 5th, 6th, and 7th; N.C.S. and Kingston, the 11th and 12th; while Birmingham is fixed for the 12th and 13th, one week earlier than usual, and I have no doubt of the wisdom of the step. When an early season like recent ones is experienced, it is wonderful what the delay of a week will do towards damaging the prospects of an exhibition. On the same dates as those chosen for the noted midland counties Exhibition will be held the Bournemouth and Croydon Shows. But how can the same date be equally good for the blooms in such widely separated districts? Surely they are a week earlier in the south than in the midlands. Already healthy signs of activity appear in the western and south-western counties for the coming November. Torquay, Taunton, and Exeter are planning their arrangements for dates early in the month of November—a commendable arrangement, evidently, when the warm nature of these localities is taken into consideration.—E. MOLYNEUX.

NOTES ON PLANTING.

WE often gain as useful instruction from the results of bad practice as from details of the most perfect operations or the most scientific bearing of a question relating to the operations of the gardener. Indeed, were we candid enough to avow our errors and record them, I am not sure if that would not be, at times, the best portions of our instructions. At any rate I shall here record, in the first place, how I was first taught to plant a tree. A hole being made large enough to hold the roots, and as deep as would allow of the tree being planted as far in the ground as it formerly stood, the roots were spread evenly on the bottom, and then a few spadefuls of soil thrown over them; the tree or bush was now shaken up and down and, may be, sideways, in order that the soil should crumble down among the roots; a few more spadefuls thrown in, and another shake or two, and so on till the hole was kept full; then two or three stamps with the foot were given, to steady the plant, and this barbarous work or mischief—which you will—was finished. Let us now analyse this process from beginning to end, and see what we can make of it. In the first place, the hole was large enough to hold the roots without cramping or twisting them round it; so far so good, but it ought to have been larger—even if it had been in a piece of garden ground that had been dug and trenched times out of mind—in order to allow the new formed roots to pass on in straight lines, instead of having to grope about for a free passage, which probably they would soon find in this garden ground. But let us suppose the planting to be done in a new piece of ground that had not been disturbed for years, and the case is very different. How the young roots are to escape from a confined space in such hard soil is more than what many planters can tell, or even guess at; and yet this is not the worst part of the tale. The roots were spread out regularly, that is, not one of them crossing another, but drawn out from the stem like lines—nothing could be done better; then a little mould was thrown over them—all right and proper too; but now we are ordered to shake the tree, to let the soil fill in among the roots. You pull it up gently, it is true; shake it two or three times, and then let it down in its place again, and the mischief is accomplished. How? You can't see it. Of course you cannot—it is below the surface; but can you not perceive that, when you pulled up the plant to shake it, all the roots followed, and, on a moderate calculation, were thus displaced full 6 inches; that is, the points are 6 inches nearer the centre of the hole than they were when we laid them down? Every one of them must have been doubled up into loops, as they could not be pushed forward into their former position through the soil, unless they were made of cast iron, or something else that would not yield; or, if they are brittle, as many roots are, they would snap like glass sooner than they could be pushed back through the soil into their former places; and thus many an honest man laid the foundation of bad diseases in his best shrubby plants—rendering them liable to the attacks of insects—to be covered with moss and lichens, and all other casualties to which sickly or stunted plants are liable. I could instance a lot of young Thorns that had been planted twelve years since after this fashion, that have not yet made 6 inches of young wood, and, to this day, they look the pictures of misery and bad management. But I have said enough to warn the young planter against this way of planting, and now let us see how the thing should be done.

If the soil is at all dry at the bottom, no matter how poor it may be, it should be stirred or trenched 3 feet deep for garden planting—that is, for ornamental trees and shrubs, and for hedges. In the case of single plants, where a pit or hole is only required, the narrowest diameter ought to be 4 feet, and if the bottom soil is poor it should be removed and some added instead; but loose soil of this description will subside in time, and if the plants are tied to stakes, as many need be to keep them firm the first year or two, the sinking of the soil from under the roots may cause them to strain, or otherwise injure them by cracking and letting in the dry winds to them. Another evil is that when trees thus planted sink down gradually additional soil is placed over the roots to make the surface level, and this is equivalent to planting too deep in the first instance, and deep planting is always to be avoided. Therefore the loose or new soil beneath the roots ought to be gently pressed down, and the pit filled up to near the surface of the ground, or say to within 3 or 4 inches of it, so that when the tree or bush is planted the surface of the pit will appear a little mound several inches above the surrounding surface. Some good planters make mounds much higher to allow for settling, but I prefer pressing the bottom soil in the first instance. One might say of this, Why loosen it at all if you press it

down again? The reason is to have a perfect drainage under the roots, and to encourage the strongest of them to run deep in the ground, which will give the plant greater vigour. We plant fruit trees shallow and on hard bottoms to prevent their getting too luxuriant, but in gardening for ornamental trees the more healthy and vigorous we can grow them the more ornamental they will be, unless, indeed, they are rather tender for our climate, in that case shallow planting on a solid or unloosed bottom suits them best, as they cannot grow so strong, and will therefore ripen better.

All this being understood and settled, let us plant a moderate sized bush to begin with—say a Portugal Laurel, for instance; it has been well taken up, has some long bare roots and a host of small fibres, with a considerable ball of soil attached close up to the bole or bottom of the plant; this ball we place in the middle of the prepared pit, and we find that the ball is so thick that those strong roots cannot lie down level on the surface, but “ride” or hang loose some inches above it. What is to be done with them? Hook them down to the surface, or lower the bottom of the hole? No, that would be bad planting again. We must fill in the loose soil under them, that they may lie in their natural position, and in doing that the small fibres are pressed down too much perhaps; if so, loosen them back again, and fill in any cavities under the bole or main roots. We shall now suppose that the whole under-surface of the ball is resting on the soil, and also all the roots, great and small, and each of them branching out in straight lines, or as regular as they can be placed. Some of the lower ones will be out of sight, but the majority are still in view. If we had a little better soil from a compost this would be the proper time to throw it over the roots; not at random, however, for fear of displacing the fibres. Take a spadeful, and throw it past the stem of the plant on the roots on the opposite side to you, so that the soil runs along in the same direction as the roots. If you throw it on the roots next to you it will run against their direction and turn back their small points, which would be nearly as bad as the old way of shaking the plant up and down at this stage. When all the roots are covered an inch or two the watering pot must come, with a large rose to it, and you must water all over the surface heartily, even if it is a rainy day. This watering is to do the business of the old shaking—settle the finer particles of the soil about the roots; the rest of the soil, to the depth of 4 or 5 inches, may be thrown on anyhow, if the lumps are broken small, so that the surface is pretty smooth, and formed into a shallow basin to hold the future waterings. A stout stake, or stakes, according to the size of the plant, should be driven down before the earth is put over the roots to tie the plant to.

All that occurs to me farther on the subject is that when large bushy evergreens are to be removed their branches must be tied up towards the stem by passing a rope or strong cord round them before commencing the roots. When you come to a very large Portugal Laurel or a common Laurel, or indeed any very large shrub that has overgrown the space allotted to it, and it is so far encroaching on other things that it must be removed in some shape or other, what is to be done with it if it is too big to remove? A plant 50 yards round is no joke to transplant, and I know one as large. Cutting back the longest branches will keep it in check for many years; but that is not the point, but that this very large plant must either be cut down and grubbed up for the wood-yard or be transplanted.

All gardeners have met with such cases, and no doubt disposed of them easily enough, but I have a new method of dealing with such as cannot be transplanted, which I have adopted for some time, and which promises to be the best hit I have made for many years. It is to cut them down to within a couple of feet of the ground. I have tried spring cutting, but it does not answer half so well for the purpose. When the stumps begin to shoot next April they are cut close to the ground, and soon a host of strong suckers will spring up as close together as those of a Raspberry bush. After a while, when they are strong enough to bear handling, you begin to cut out the weak ones, till the whole have room enough to grow away freely, which they will now do in earnest, and as straight as fishing-rods or gun-barrels. I have seen strong shoots from a common Laurel stool of this kind reach up to 10 feet in one season, and they often attain from 6 to 8 feet. Now, what I propose to do with these strong suckers is this—to make clean stemmed trees or standards of them. Many attempts have been made to obtain fine standards with clean smooth stems to them of our more common bushes with various degrees of success. The Portugal Laurel treated thus is a good imitation of the fine standard Orange and Lemon trees of Italy, and the common Laurel is not much behind it. Any of the varieties of the common Phillyrea may thus be made to imitate the narrow-leaved Myrtle of the south of Europe, while the common Alaternus might be mistaken at a few yards' distance for the broad-leaved Myrtle, if reared up on a 5-foot standard with a close circular head, and to imitate the Olive as a close-headed standard take an overgrown old Privet plant, cut it as above, and you will soon have a dozen of them. I have seen for this purpose whole Portugal Laurels stripped of their side branches up to 5 or 6 feet high, and the tops formed into circular heads, but the wounds and scars left on the stem—unavoidably, it is true—where the great side branches were lopped off were most hideous to my eyes, and so ungardening-like that I would as soon live in a desert as be surrounded with such ugly and haggard-looking objects.

But to return to our suckers, from which these very handsome imitation plants are expected. As soon as they are from 5 to 7 feet high nip off the points to stop them, and the next half dozen buds below will start into side branches, which are to form the foundation of the future standard, therefore see that they are at proper distances from each

other. The situation of the buds will determine this before any branches are formed, and if the buds are too close together disbud them, so as to allow room enough for the future branches. If any side shoots are made lower down, either after stopping the points or before, they must be nipped before they form one joint, and only the leaves from which they issue left. All the leaves on the stem from top to bottom are left on the first season, but no side branches allowed, except the few at the top, to form the head. When the young wood gets firm, say about August, you may begin to cut out the buds, beginning at the bottom and going up progressively as the wood ripens, so that by the end of the first growing season all the buds on what is to form the future stem are entirely got rid of. This is the most essential part of the whole process, but the buds ought to be extracted—yes, that is the right word—extracted without injuring the leaves, for unless the buds are taken out with their roots, so to speak, depend on it they will trouble you afterwards by throwing out strong side branches; but once extracted from a one season's growth no tree, I believe, has the power of renewing them a second time. These suckers may be safely left attached to the mother stools for three years or more, for they will acquire more strength and come sooner into use that way than if taken off sooner. Any time during the spring of the second season a ring of bark, about 2 inches wide, must be taken off the bottom of these suckers, and the lower down the better; then, when these wounds are perfectly dry, and the upper edges of them begin to swell by the formation of new wood, and not before, you may earth up some good soil all over the old stool, till it is 4 or 5 inches above the ringed parts. Roots will immediately issue from the swellings of these rings, and so form you a tree "on its own bottom." By the help of these roots and the connection with the parent stock very vigorous healthy young trees are formed in less time and more handsomely than by any other process known to us, and in separating them from the stool work your way to the ringed parts and cut through them with a small saw, and this you may do twelve months before you finally remove your new standard.—D.

LAST week we had the pleasure of greeting our readers with the good old wish with which so many are familiar at Christmastide: this week we add the no doubt equally ancient and not less pleasant refrain—

A HAPPY NEW YEAR TO ALL.

— **EVENTS OF THE WEEK.**—On Monday, Jan. 6th, the National Chrysanthemum Society's General Committee will meet in Anderton's Hotel at 7 P.M., and the same Society's midwinter Exhibition will take place on Wednesday and Thursday, January 8th and 9th, in the Royal Aquarium, Westminster. A conference of Chrysanthemum growers is also being arranged for Wednesday afternoon.

— **THE WEATHER IN THE SOUTH** has been somewhat colder, with frequent frosts and slight snow on several nights. Around the metropolis frosts and fogs have been prevalent, the latter on two days (Sunday and Monday) being exceptionally dense even for London, causing a remarkable darkness, which on Monday continued the whole day. In low districts 12° and 14° of frost have been registered.

— **THE WEATHER IN THE NORTH.**—The weather during the last fortnight has continued extremely variable. Some snow fell between December 21st and 22nd, and laid for a day. Frost of 5½° has occurred. Throughout the night of the 25th the thermometer stood at 45°; at 9 A.M. on the 17th, at 51° Fahr.; a gale of wind followed within forty-eight hours. Generally mild and drizzly weather has been the rule.—B. D.

— **PRESENTATION TO MR. HALLIDAY.**—The young gardeners at Alton Towers, as a token of the great respect they had for Mr. Rabone's foreman, Mr. Halliday (who served nearly five years in the above capacity), presented him with an address and writing case on his appointment as gardener to Lady Forester, Meaford Hall, Stone, Staffordshire.

— **GARDENING APPOINTMENTS.**—Mr. Richard West, late gardener at Preston Hall, has been appointed head gardener to Bazley White, Esq., M.P., Genning's Park, near Maidstone, Kent. Mr. W. Hagon, for the last twelve years head gardener to James Skinner, Esq., Bramley Hill House, has been reappointed head gardener to A. H. Knight, Esq., at the same place. Mr. Charles Marr, foreman, North Marine Park, South Shields, has been appointed head gardener to Mrs. Liddell, Prudhoe Hall, Northumberland.

— **GESNERA EXONIENSIS** is a useful old plant. By lamp or gas light it has a telling effect, the orange scarlet flowers and dark velvety foliage being extremely bright. During its growing season it must be placed in a shaded and moist stove, as it very much dislikes either an arid atmosphere or bright sun. It is also partial to a good proportion of leaf soil in the potting compost.

— **BEGONIA SOCOTRANA.**—This is likely to become very popular. Our plants are now unfolding their rosy pink flowers, and are very attractive. Those varieties raised by Messrs. Veitch—i.e., John Heal and Adonis, of which socotrana is one of the parents, we also grow, and they are a good addition, as they form a fresh class of winter flowering Begonias. It must be understood that these remain dormant during the greater part of the summer, and also require rather severe resting. If kept out while at rest they are apt to decay.

— **IN addition to the above as WINTER FLOWERING PLANTS** there are Poinsettias, Euphorbias, Lily of the Valley, Roman Hyacinths, &c., double Primulas, Tea Roses, Marie Louise Violets, and where grown there are several other useful Orchids for blooming during the winter season. For instance, there is the old and well tried *Cypripedium insigne*, *Laelia anceps*, *L. albida*, several *Dendrobiums*, such as *D. nobile*, *D. Ainsworthi*, *D. Wardianum*, *D. aureum*, *D. formosum giganteum*, *Cattleya Bowringiana*, *Cymbidium Mastersi*, and *Zygopetalum Mackayi*. The above are very reasonable in price, and may all be grown in the ordinary plant stove.—A YOUNG.

— **MR. T. S. WARE**, Tottenham, sends us flowers of the *ST. BRIGID HELLEBORE*, which he considers "without doubt is the finest in the family." The flowers are large (3½ inches in diameter), pure white, of good substance, and borne in pairs on stout stems.

— **PRESENTATION TO MR. A. D. CHRISTIE.**—At a recent meeting in Warwick Mr. A. D. Christie, who was for many years head gardener at Warwick Castle, but who has now entered upon an engagement of a similar character at Ragley Hall under the Marquis of Hertford, was presented at the Court House with a purse of gold and an illuminated address by residents of Warwick with whom he has so long been associated. The Mayor (Alderman Cooke), who made the presentation, presided, and there were also present Alderman Stanton, Major Mason, Messrs. R. Laurie, Lloyd, Evans, R. Greenfield, Hammond, Wilson, Payton, Hotchkiss, and many others. There were 120 subscribers to the fund.

— **MESSRS. FOSTER & PEARSON** desire us to notice their new *BEESTON GREENHOUSE*. It is portable, and so designed as to be erected by any handy man. The roof sashes are moveable, and can be fixed in any position for ventilation, while screws or similar fastenings are not required for making them secure.

— **TOMATO MIKADO.**—I was captivated with the handsome proportions of this variety as shown in some seed lists, bought a 2s. 6d. packet of seed, cultivated the plants with the greatest care, and was rewarded with the most inferior crop I ever saw on a Tomato. The fruits were rarely smooth, the majority decidedly ugly, and all so scarce as not to pay for attention. I discarded it without the slightest regret.—J. M.

— **CHIMONANTHUS FRAGRANS.**—This deciduous shrub may be grown as a wall climber, as it shows to the greatest advantage, and succeeds the best in this way. A south wall is the best, but on an eastern aspect it grows and flowers freely. At the present time it is covered with buds, and there are a few open flowers, the fragrance from which is charming. The flowers are not very imposing, but the time of the year when they open and their delightful perfume render it worthy of a place in any garden where winter-flowering shrubs are appreciated.—M.

— **CHRISTMAS ROSES.**—It would amply repay any lover of this well known flower should he have the opportunity of seeing some excellent clumps in the gardens at Col. Clarke's, Charlton House, Shepton Mallet. They are the finest I have ever seen, and are grown on a south border, planted in a good loam. The specimen blooms which I enclose are picked from clumps averaging between 200 and 300 blooms on each plant. They are covered with a small rude frame. It is evident from their good appearance that Mr. Woollen accords them judicious treatment. [The blooms received were large and pure white; such specimens prove very useful.]

— **GARDEN BIRDS.**—I have no doubt that the birds seen by Mr. Murphy searching for insects on his Chrysanthemums were *colletis* (*Parus ater*). The lesser spotted woodpecker has a red head and

would not be likely to perch on anything so unsubstantial as a flower. I do not at all think that bullfinches devour fruit buds for the sake of any insects concealed in them; and as some people are sure to continue to say that they do, it would be well if some of those who have these birds in their gardens were to follow Miss Ormerod's suggestion, and send up the contents of their crops for microscopical examination by an expert.—W. R. RAILLEM.

— THE annual meeting of the RICHMOND (SURREY) HORTICULTURAL SOCIETY was recently held at the Greyhound Hotel, Sir J. Whitaker Ellis presiding. The balance in hand is £28 7s. 2d. Mr. Gribble having tendered his resignation as Assistant Secretary, was presented with a handsomely illuminated address on vellum, as a mark of appreciation of his useful services during the past five years.

— WARE AND DISTRICT HORTICULTURAL MUTUAL IMPROVEMENT SOCIETY.—An ordinary meeting of this Society was held in Ware on the 17th inst. There was a good attendance of members. Mr. R. Smith was voted to the chair. The subject for the evening was "Chrysanthemum Culture," by Mr. G. Fulford. The paper dealt with the chief points in their culture, and a discussion followed by Messrs. Brown, Wiltshire, and Pavey. The meeting terminated with the usual votes of thanks to the Chairman and essayist.

— THE PLAGUE OF RATS.—Writing to the *Standard*, "John Rodent" says:—"I beg to send you a simple means of destroying large numbers of these vermin. Fill a large barrel three parts full of chaff. Place a quantity of barley meal or other bait on top of the chaff; place a board, sloping from top of barrel, for rats to jump on top of chaff, but not to come within 6 inches of it. Rats can thus have a feast and escape. The following night fill the barrel three parts full of water, place about 4 inches of chaff to float on the top, bait as before, and in the morning you will find the barrel half full of drowned rats."

— THE DURHAM, NORTHUMBERLAND, AND NEWCASTLE-UPON-TYNE BOTANICAL AND HORTICULTURAL SOCIETY.—We learn from the report of the Council of this important Society that the fine autumn Exhibition held on the occasion of the visit of the British Association to the city was not a financial success in consequence of wet weather on the whole of the three days. Still the receipts amounted to £519 5s. 1d. The deficiency was made up by a concert, and the Leazes Park Committee considerably waiving a great portion of the rent. The Council announce a great increase of membership, and confidently expect the subscription list will be so enlarged in 1890 that the income will meet the expenditure even in adverse weather, leaving a surplus to form a reserve fund. The receipts from all sources during the year were £1532 9s., and the expenditure £1462 7s. 11d., balance in favour of the Society £70 1s. 1d. The Society is to be congratulated on having such earnest supporters, and we trust it will have a prosperous career.

— LUCULIA GRATISSIMA.—I enclose a photograph of the above shrub, grown against a pillar in the conservatory here, covering it 20 feet high, and flowering freely from the top to the floor. The large trusses of flowers of a pleasing pink deliciously scented, with the vigorous dark green leaves, have been the admiration of many who have seen it this autumn. The plant is at least twelve years old, planted in loam with a little peat and sand, thoroughly drained, and watered occasionally with liquid manure made from artificial and stable manures. The plant is pruned at the end of January, and cut back to within a joint of where previous cut, or spur-pruned. The conservatory is large, and is heated from September to May 50° to 55° at night, and the plant is much exposed to the sun from the roof. This is the finest plant of its kind that I have seen, and is worthy of more general cultivation. We have not found the flowers useful for cutting purposes.—G. HARRIS, *Alnwick Castle Gardens*. [The photograph shows that the plant, which we remember well, is an extremely fine one, and is flowering most profusely, but it was too indistinct for reproduction by engraving.]

— MR. H. C. RUSSELL, Government Astronomer of New South Wales, has published the results of METEOROLOGICAL OBSERVATIONS made in that colony during 1887. The number of reporting stations is now 862, being ninety-four more than in 1880, the increase being almost wholly in rain stations. The arrangement of the tables, which give the most important data for each station separately, is the same as in previous years; but there are also two new tables giving the mean maximum and minimum temperature at Sydney for each month from 1856 to 1887. The mean temperature of the whole colony for the last seventeen years is 61.2°. At Sydney the mean for thirty years is 62.7°. The diagrams appended to the volume give a good idea of the weather

conditions at Sydney, and clearly exhibit the peculiarities of certain periods, such as the very short winter of 1873, and the long one of 1874, also the long summer of 1877-78, with four months of hot weather, and the short summer of 1886-87, when there was only one month of hot weather. In 1878 the lowest winter temperature occurred in June, and in 1872 in August. A comparison is made of the rainfall at the principal places in the various colonies. The contrast between the amount at Brisbane and Sydney and that at Melbourne is very striking. At the former places as much rain sometimes falls in one month as would make a year's rainfall at Melbourne. At Sydney the least annual rainfall on record is 21.48 inches, and the greatest 82.81 inches. The question of evaporation continues to receive considerable attention; the tabular results are published, with the rain and river results, in a separate volume.—(*Nature*.)

— THE WIMBLEDON AND DISTRICT ROYAL HORTICULTURAL AND COTTAGE GARDEN SOCIETY held their annual meeting at the Lecture Hall recently, and Dr. G. Walker presided over a good attendance. The seventeenth annual report stated that both the summer and autumn shows maintained their high standard of excellence. The entries were numerous, and in all the classes the competition was fair. At the National Chrysanthemum Society's Show the Wimbledon Society won the trophy which is offered every year for competition among the forty-three affiliated societies. The report stated in conclusion that Mr. W. B. Faulkner had generously offered a challenge cup, value 15 guineas, and 5 guineas as a first prize for the autumn show, and the Committee trusted that others would follow his good example. The accounts showed a balance in hand of £2 6s. 2d. The receipts amounted to £242 16s. 10d., and the expenditure to £240 10s. 8d. The subscriptions amounted to £166 9s. Mr. A. Hutchinson thought the time had arrived when they should appoint a paid secretary. Although in this instance a dual government had worked very well, yet in nearly every other instance a dual government tended to disorder. He objected to it on principle, and moved that Mr. Lyne be chosen Secretary for the ensuing year. Mr. Neller seconded the motion, but Mr. Lyne declined the offer, observing that he would probably be leaving Wimbledon in two or three years' time. He was, however, quite willing to work jointly with Dr. Walker gratuitously if the Society saw fit to elect him again. Ultimately Mr. Hutchinson withdrew his motion in deference to the feeling of the meeting, and Dr. Walker and Mr. Lyne were re-elected joint Honorary Secretaries. Sir Edwin Saunders has presented the Society with a handsome banner for use at the annual shows.

— DOWDY GARDENS.—Some gardens have a look much worse than that of neglect; they are "dowdy." One cause for this is overcrowding. The plants have neither room, light, nor air sufficient to enable them to develop their forms of flowers. Not long since we saw a bed of Balsams of fully fifty plants in a space 1½ foot square; the owner complained bitterly because his flowers were not so fine as ours, yet our plants occupy 6 square feet each, and they completely cover the space. Plants should be thinned soon after they are started to get a strong healthy growth. Another common cause of dowdy gardens is a desire to have a little of everything in a space only sufficient to grow a few things well. Form and colour are so intermixed that the effect is destroyed; no harmony, no distinctness, simply a jumble of colour. And still we are asked to admire flowers under such conditions. As well might we call an artist's palette a picture. In the window garden the same thing is noticeable. Ten times as many plants as look well or do well, are crowded into a given space, for fear they will be killed in the garden. Better have them killed by Jack Frost than to starve them in the house or let them eke out a sickly existence. A plant is never so beautiful as when it is grown to perfection. This cannot be done if it is crowded, or in the shade of trees or walls. It is better to have a single specimen in the vigour of health and bloom than a floral hospital. A single plant of a good Zinnia will adorn a garden for three months; whatever its colour may be, there will be none other to destroy its harmony, and there is no colour but what is pleasing if it does not suffer by comparison. Plant a few things, and give them a living chance.—(*American Garden*.)

THE NAMES OF PLANTS.

In explaining this digest of Rose statistics in the last issue of the Royal Horticultural Society's Journal, the Rev. W. Wilks has the following remarks upon nomenclature that are worth a careful perusal:—Beyond the mere clerical work the chief difficulty has arisen from varying nomenclature, and that not only with regard to synonyms, but also in regard to the very varied spelling of names. Great confusion is evidently caused by that most reprehensible practice of raisers of new

sorts, in giving to their offspring names almost identical with others already existing. For example, Mme. Eugène Verdier (H.P.) and Mlle. Eugénie Verdier, and then repeating Mme. Eugène Verdier again as a Tea! The result of this kind of naming is that "Madame" and "Mademoiselle" become completely mixed. Sometimes one is entered when the other is evidently meant, and more often we get a hybrid form of name, in either "Madame Eugène V." or "Mademoiselle Eugénie V.," both hybrid names appearing also as Teas! Other examples will at once suggest themselves—e.g., Hippolyte Jamain and Mme. Hippolyte Jamain (H.P.), and Mme. Hippolyte Jamain (Tea); Jules Margottin and Mme. Jules Margottin and Mme. Margottin; Mme. Ducher and Marie Ducher and Jean Ducher; Mme. Scipion Cochet (H.P.) and Mme. Scipion Cochet (Tea); Princess of Wales (H.P.) and Princess of Wales (Tea); Prosper Laugier and Mme. Prosper Laugier; Julius Finger and Jules Finger; Jules Chrétien, an old worthless pink H.P., and Jules Chrétien H.P. (Schwartz, 1878), a handsome dark one; Souvenir de Victor Hugo (H.P.) and Souvenir de Victor Hugo (Tea); Baron Nathaniel de Rothschild and Baronne Nathaniel de Rothschild, both H.P.'s; and so on *ad infinitum*. Or is our language so poor in names that we need have two so similar as Lady Sheffield and Lady

half—which half, by the way, would do for the next new Rose—e.g., Archduchess Maria Immaculata might very well be content to be simply styled "Archduchess." "Immaculata" would then make an admirable name for the next new white Rose, and we should have "Maria" over and to spare. Prince Camille hardly needs "de Rohan" added, any more than Souvenir d'Elise requires "Vardon;" Princess Mary could well do without "of Cambridge;" Madame E. de Bonnières de Wierre could surely spare "E. de Bonnières" for some other flower and really not feel the loss; and the promised new Rose of 1890 might be content to submit to the inevitable, and be from the outset what she is bound to be in the end, "Dowager Duchess," leaving Duchess of Marlborough for some future novelty. I seriously think this question of simplicity and distinctness of nomenclature is a matter rosarians would do well to lose no time in grappling with.

A GOOD MELON—THE COUNTESS.

AMONG the great numbers of Melons that were examined by the Fruit Committee of the Royal Horticultural Society last year not one

FIG. 2.—THE COUNTESS MELON.

Suffield? Raisers might surely exercise a little ingenuity in choosing really distinctive names for their new introductions. Nor can I think the constant harping on one string, however distinguished, tends to clearness—e.g., Paul Verdier, Eugénie Verdier, Victor Verdier, Mme. Eugène Verdier (H.P.), Mme. Victor Verdier, Emilie Verdier, Marie Verdier, Souvenir de Victor Verdier, Mme. Eugène Verdier (Tea), and probably several others. Similar lists might be made of Jamains, Margottins, Levets, Lyons, Lyonnaise, &c. Nor are our neighbours across the Channel alone in this, for amongst English names we have Beauty of Waltham, Glory of Waltham, Pride of Waltham, Queen of Waltham, Star of Waltham, Waltham Climbers Nos. 1, 2, and 3; Glory of Cheshunt, Grandeur of Cheshunt, Brightness of Cheshunt, Cheshunt Scarlet, Cheshunt Hybrid. What wonder if the average gardener gets altogether "mixed" with such a repetition of the dominant name! Surely one can have too much of such great Rose names as Verdier, Cheshunt, Waltham, Lyons, &c.? And might we not usefully drop at least half of the multitude of Madames and Mademoiselles, and most of the Souvenirs; indeed, all of them, except when needed for the sake of clearness? Might we not, for instance, without any disrespect or undue familiarity, talk of Alfred de Rougemont, Alphonse Lavallée, Bellender Ker, Charles Crapelet, Clemence Joigneaux, Gabriel Luizet, Norman Néruda, Eugénie Verdier, Marie Cointet, Marie Rady, Thérèse Levet, Angèle Jacquier, Caroline Kuster, Gabrielle Drevet, Admiral Courbet, Riza du Parc, &c., &c. Some of the very long names might well drop

met with greater approval than this. The Countess, as it was exhibited by its raiser, Mr. J. H. Goodacre of Elvaston, seemed to possess a combination of good qualities, productiveness, size, appearance, and flavour being so markedly represented that all hands were promptly held up for a first-class certificate. The fruit is yellow in colour, distinctly netted, thin in the skin, thick in the flesh, which is nearly white, tender, juicy, and pleasantly flavoured. The character of the variety as it was exhibited is accurately displayed in the engraving, fig. 2, for which we are indebted to Messrs. James Veitch & Sons, who are introducing the Countess to the Melon-loving public; and persons who grow this variety as well as it was presented by its raiser will have reason to be satisfied with it and themselves.

LILY OF THE VALLEY.

MY answer to your correspondent Mr. Coombe, on page 503, as to why I prefer a substantial loam for the growth of this plant, is very simple—viz., that having seen it growing naturally in such a soil, and having noticed it produce the best results, I naturally recommend such for its cultivation. Without doubt it flourishes well in a good rich

loam. Mr. Coombe's method of forcing them in cocoa-nut fibre refuse is very satisfactory, but all gardens have not the means or convenience for such a practice as Ashton Court. In a great number of places cocoa-nut fibre is considered too expensive. If the majority of gardeners had the means and conveniences of the minority foreign produce would not glut the markets to such an extent as it does at present.—A. G. F., *Whitstone*.

BOUVARDIAS.

WHEN well and properly grown Bouvardias will continue to yield a succession of their flowers over a period of several months. Unfortunately they are not so well grown in private gardens as they deserve to be, though in market establishments they are well treated with the best results. The principle, however, upon which these are grown to have the majority of the flower trusses open at one time is not exactly the one that should be followed when a lengthened succession is required.

If the plants are dried rapidly death in many cases will result. Their wood is soft, and this must be hardened and ripened, then they can be dried without fear. They are similar in this respect to Fuchsias, and ripening their wood and resting period should be much the same as generally accorded, the principal difference being the temperature in which the two are kept while at rest. That for the Bouvardia should not be lower than 45°. Very few would think of drying the Fuchsia while its wood was green and soft, but quickly grown Bouvardias have been given this treatment with the results pointed out.

Bouvardias are propagated by cuttings and portions of root, and when the object is to produce good specimens in one season without resorting to express methods of culture and excessive feeding it is important to make an early start. Those I have described would have a much more limited rest than they would be allowed the following season. After the wood is thoroughly hard keep the soil dry for two or three weeks, and then prune back to within 3 inches of the base; turn the plants out of their pots, shake the whole of the soil from their roots, and remove a few of the strongest from each plant. The stock should then be placed into 3-inch pots, and transferred to a vinery or Peach house. Plunge the pots in boxes about 6 inches deep in cocoa-nut fibre refuse, leaves, or any other material, covering the surface of the soil to prevent evaporation. If the plunging material is kept moist and the plants gently syringed daily they will need no water at the roots until they start into growth. The boxes can be placed upon the pipes. Start the plants in any structure where the temperature does not fall below 50° at night, and is gradually increased. A gentle hotbed is a capital place for them. The amateur who has limited accommodation in this respect can give his plants a more lengthened period of rest, and start them in the same way as he does Fuchsias, or in a slight hotbed that may be made for raising seeds. Any plants raised in this way require two seasons instead of one in which to produce useful flowering plants.

When once a stock has been obtained it is a good plan to adopt a two-years system of raising plants. This is decidedly better even when they are required for decoration in pots or yielding flowers in succession for cutting than depending upon either cuttings of young wood or roots every season. To carry out this plan strong roots according to the quantity required should be taken from strong old plants started into growth in February. Cut these into lengths of about half an inch and strew them on the surface of boxes nearly filled with soil composed of equal portions of leaf mould and loam; scatter a little sand amongst the portions of root and cover them about a quarter of an inch deep with fine sandy soil. Place the boxes in an intermediate temperature, when shoots will soon appear above the soil. Encourage the young plants to grow, and gradually harden by the end of June, so that they can be stood outside fully exposed to the sun. The boxes will be one mass of growths. In September place the plants in a cool house and gradually allow them to rest, then keep them dry. When the time arrives for starting them into growth the soil should be shaken from their roots, and each plant placed singly into 2 and 3-inch pots. They should be pruned to good "eyes," 2 inches above the soil. The cultivator in possession of plants of this nature is a long way in advance of those who rely upon raising them either from roots or cuttings in spring.

Cuttings of young shoots root readily enough in the propagating frame in brisk heat. The shoots selected must be soft, or they are a long time forming roots. Cuttings 2 inches long will do; it is not important whether they are cut close to a joint or not, but this we usually do, and insert them with the two lower leaves attached. One joint, however, should be left on the plants from which cuttings are taken, when they will soon "break" again, and be none the worse for the removal of the cuttings. When the cuttings are rooted place them singly into small pots at once, and

directly signs of growth are visible the point should be removed. Some cultivators prefer plants raised from cuttings of young wood before those raised from roots, because they are not so prolific in throwing up from the base. A more shapely plant can perhaps be produced by the former; but in spite of this, we prefer for the object we have in view those raised from portions of roots. A strong shoot or two from the base of these by the time they are placed into 5-inch pots is the making of good plants the first season.

Whether the plants are raised from cuttings of young wood or roots or are cut-backs, they need the same treatment after they are started into growth. Those started and raised early should be kept in a temperature that does not fall below 60°, and as they advance in growth the temperature may be gradually lowered until they can be grown in cool houses or cold frames. From the first attention is needed in pinching, and the point of the shoot should be removed after each pair of leaves. This induces the formation of two shoots, which, when they reach the same stage, are again pinched. This practice is continued until the end of June. If they are to be kept under glass the whole of the season it may be continued until the middle or third week of the following month. When suckers spring from the base they are pinched at the first pair of good leaves they make, and then are treated the same as the remainder.

The question arises at this stage whether they are to be planted out or kept in pots. At one time the luxuriant growth that they made tempted the recommendation of the former method. They do very well, and flower well in some seasons; but the strong growth is misleading, and however carefully they are lifted they are seriously checked. We strongly advise keeping them in pots and plunging in an open sunny position until September. When the nights have a tendency to be cold the plants should be placed in a light airy structure at first.

Bouvardias should be repotted from time to time as they need more root room, giving them their last shift when plunged outside. If raised from cuttings early they may be placed in 30's—4½-inch—in May, and those from roots into 5-inch, which are large enough for the first season, while cut-back or two-year-old specimens raised in boxes may have 6-inch to 8-inch, or even larger pots. When they are large enough at starting time for 5-inch pots one other shift only is given—namely, into 8-inch. In fact, all plants that are cut back, except very small examples, are only shifted once to save labour.

The pots must be carefully drained, and the soil should only be moderately firm at first, and it may consist of the loam used for Cucumbers and Melons with the addition of about half leaf mould and sand. Failing this some that has been stacked with the same additions is excellent. At the final potting one-third leaf mould only need be used, and the soil may be pressed firmer. Take care that they do not become root-bound while in small pots, for this has a tendency to check and harden their wood prematurely and tells against full development of the growth.

Supply water carefully after the plants are started, and again after they are repotted. Once the soil is well filled with roots liberal supplies should be given them. From the time they are started until they have ceased flowering the soil should never be allowed to become dust dry. If this takes place their fine roots are scorched. When the pots in which they are to flower are filled with roots weak soot water in a clear state may be given every time water is needed, and then this and liquid made from cow dung alternately. If the latter is not at hand artificials once a fortnight may be applied to the surface of the soil. The syringe from the first may be used daily or twice a day, according to the weather, and continued for a time after the plants are housed and accustomed to the change.

The treatment after they are housed is simple. They need plenty of light and air at first; after a few weeks the latter can be dispensed with, and a temperature of 55° to 60° maintained according to the weather. Not only will terminal trusses be produced, but the strong shoots that extended from the time pinching ceased will break again into growth and continue to yield serviceable flowers. This cannot be expected from plants that are grown rapidly and the wood is practically soft at flowering time. Plants such as I have described can, after they cease flowering, be gradually dried and kept as dry as it is wise to keep Fuchsias without the slightest fear of losing them.

The following are amongst the most useful:—Doubles.—Alfred Neuner, white; President Garfield, blush or pink; Hogarth fl.-pl., scarlet. Singles.—Scarlet, President Cleveland, the brightest of all; Hogarth, Dazzler, Elegans, Flavescens, yellow; longiflora flammea, blush rose; Priory Park Beauty, pink; Queen of Roses, bright pink. Single whites.—Humboldt, corymbiflora, Vreelandi, The Bride, not quite pure white; jasminiflora, true; and alba elegantissima.

If six only are needed select the first, second, fourth, tenth, twelfth, and thirteenth.—WM. BARDNEY.

PRESERVING PLANTS IN WINTER.

WE are now in the midst of the worst period of the whole year for preserving plants, and if they can be successfully kept for the next six weeks or so they will give little trouble afterwards. With plenty of well heated glass houses all plants may be wintered as easily as they are retained in summer, but unfortunately instances of commodious and efficient accommodation are exceptions, and the great majority of growers, especially of the amateur class, are frequently at their wit's end as to where to store and how to preserve their tender plants. But it is not so much particular storage as the exercise of care that will insure success. I have known many bedding and other plants wintered in peculiar and what might be termed unsuitable places. It is a mistake to give store or stock plants too much heat in winter. This keeps them growing when they ought to be resting, and the more they grow in midwinter the more tender they become, as there is nothing substantial in the growth formed now. They ought to be well hardened by the end of October, and kept in that condition. Cold, short of actual frost, will rarely harm any plant, provided the foliage and atmosphere are dry. This is the great secret of successfully preserving all plants in winter.

Our Orange trees, which are wintered in an unheated house, would suffer severely from excessive damp were it not that the greatest care is exercised in watering, and they are kept decidedly dry at their roots. Some of them do not receive any water for four weeks at a time, and it is astonishing how luxuriant they remain. Through the deficiency of pipes in the Pine house the temperature is frequently down to 35° or 40° in winter, and rarely rises to 50° with artificial heat, and if kept damp at the roots and top in this low temperature they would soon become yellow and sickly, but by withholding moisture as much as possible they remain in fine health all winter. Store plants are rarely active at this season. They do not make any great demand for moisture, the natural condition of the atmosphere is generally sufficient to retain all their qualities, and in nineteen cases in every score deterioration is the result of superfluous moisture in the atmosphere, and especially at the roots. Whenever plants are going wrong let this point be considered at once, and it must never be forgotten in after treatment. I would rather winter plants in a temperature of 40°, and with a dry atmosphere, than in 60° and have damp to contend with.—J. MUIR.

USEFUL FERNS.

ALTHOUGH Ferns of all kinds are beautiful, yet, like other plants, some species and varieties are better adapted for decorative work than others, and in the following lists I have mentioned those that I know from experience to be useful for that purpose, as it is much better to work up a stock of a few useful sorts than to grow a greater variety, many of which perhaps are not adapted for decorative purposes; but I wish to make it clear that I do not write disparagingly of forming collections of every species and variety obtainable, as a thoroughly representative collection is always interesting, but as many varieties which are very pretty and thrive well in ferneries are quite unfit for decorative purposes, much more satisfactory results are obtained by growing in quantities those that possess the good qualities necessary.

Among Adiantums, *Bausei*, *concinnum latum*, *cuneatum*, *formosum*, *macrophyllum*, and *Sanctæ Catherinæ* are all extremely useful, the two last-named being distinct, and are not so much grown as they should be. *Davallia elegans* is one of the most beautiful of all basket Ferns. *D. Mooreana* and *Goniophlebium subauriculatum* are also good for that purpose; the last named, having fronds 6 or 7 feet long, should only be used when there is plenty of room for development. Sometimes in halls and large rooms plants of great size are placed in vases on a pedestal in such positions, this Fern forms a striking object. *Alsophila australis* and *Cyathea dealbata* are capital for placing in the centre of groups, or for standing singly in good positions. *Lomaria gibba*, *Nephrodium molle*, *Nephrolepis davallioides*, and *N. tuberosa* are also very effective and last well. The last named I have a great fancy for, for filling vases or growing in baskets, and should be grown in large quantities, as it is both novel and striking in appearance. *Platycerium alcinorne* is a useful Fern to use occasionally, on account of the remarkably curious structure of its fronds. Curiosities of this description usually attract a good deal of attention, and are therefore worth using for the sake of giving variety, and interesting many who would scarcely notice more common types of far greater beauty.

The Pterises are extremely serviceable to decorators. A few plants of the different varieties arranged amongst other plants give quite a distinct feature. To be seen to the best advantage they should be used sparingly as dot plants, so as to show distinctly the glowing outline of the individual plants and fronds. *P. argyræa*, the beautiful silvery markings shown on the arched fronds of this variety give it a character quite uncommon among Ferns, and it also has the advantage of being very attractive as well as uncommon. *P. cretica* and *P. cretica albo-lineata* are fairly effective and last well, but the real gems of the family, which should be grown in large quantities, are *P. serrulata*, *P. serrulata cristata*, and *P. tremula*. These last well in dwelling rooms, even when placed in comparatively dark corners, and when properly arranged in mixed groups aid materially in producing that glowing undulating surface which is rightly considered the correct method of artistic plant-grouping. Small plants of these varieties are also much sought after for filling receptacles for dinner table decorations, or various bronze and china figures, which have a small interstice for holding Ferns, and are generally placed in prominent positions within the drawing room or boudoir. Among hardy Ferns the following are worth growing in pots for decorative purposes:—*Adiantum Capillus-Veneris*, *Polystichum proliferum angulare*, *Scolopendrium crispum*, and *Woodwardia angustifolia*.—H. DUNKIN.

BRAMBLES.

CAN any of your readers give me any information as to the universal success of such varieties as Kittatinny, Lawton, Mammoth, Philadelphia, Snyder, Wilson junior, or any of the others of that tribe? I would gladly go by a slow train that stops at every station from Land's End to John o'Groat's to inspect them.—SOUTH WALES.

I CANNOT allow the remarks of "South Wales," on page 527, to pass unnoticed. He says, "I cannot congratulate 'De Nova' on the information he has tendered as to the great success of the American Blackberries." What does he mean? I have read his note on page 487, and the conclusion I arrived at was that "South Wales" had never either seen or heard of a good crop, and if any of your numerous readers knew of one, he would be pleased to hear of it, and as I visited Darlington in October and saw a splendid crop of the fruit in question, I informed him, "through the medium of the Journal," of the fact. I venture to think my note on page 509 does not deal with Blackberries in general as to whether they are a success or otherwise, it only deals with one particular crop that came under my notice. I, like your correspondent, have ceased to regard one swallow as making a summer; I have also ceased to regard one failure as final.—DE NOVA.

WHEN foreman at Tulliechewan Castle, Dumhartonshire, I remember the proprietor wishing to try some Brambles in the kitchen garden in order to increase their size, and the young men were sent to lift them from a bank of gravel. They were planted in an open position, staked as Raspberries, and the long rods tied from one stake to the other. They were about two years coming into a fruiting condition. After leaving I made a call now and again on Mr. Smith, the head gardener, and in walking round with him I noticed the Brambles were nearly all dead, and was told it was the severe weather in March that killed them. They had made stems 12 or 14 feet long. No doubt the strong growth was too soft, as those outside were safe enough. Perhaps this may interest "De Nova" and "South Wales." I never saw an American Blackberry in Scotland worth looking at, no need for tasting.—W. E., *Rutherglen*.

I PLANTED three plants of *Rhus laciniatus*, 16 feet apart, in January, 1883, against a south wall. In 1887 we gathered twenty-one quarts of fruit, in 1888 twenty-seven quarts, in 1889 thirty-eight quarts; on August 17th last we gathered the first quart, the last on October 20th. The longest growth made this year was 30 feet. When there is not enough new growth to take the old place, we prune the old close in, and leave what is required to cover the wall. The fruit and foliage have been admired by many. The fruit is fine and very useful.—WILLIAM KIPPS, *Walton Lea*.

I WAS always under the impression that the Parsley-leaved Bramble was an American. This I have been very successful with. Some of the branches have produced from sixty to one hundred ripe fruits, and some very fine. I have been trying different kinds for this last six or seven years, and have filled up the places of some with good English ones I have found in the hedgerows. Some of these have borne heavy crops. The Parsley-leaved Bramble seeds freely, and plants can also be raised from eyes the same as Vines, but when once established the best and easiest way of propagation is to bend the points an inch or two into the ground; they will soon strike root, and can then be planted where they are to stand for a year or two. If planted in favourable situations, strong shoots from 10 to 20 feet long will be produced during the season, and if well ripened will produce an abundance of fruit the following year. I suspect that some persons who complain about them have not planted them in situations at all to their liking. If they were to pay

attention to the surroundings of an extra fine specimen in the hedge-row, and try and imitate the conditions, we should hear of more heavy crops and fewer failures than at present. I believe the best way to grow them for profit is to throw up a mound similar to an earthed-up row of Celery, plant from 10 feet to 20 feet apart, and train the long growths similar to espalier fruit trees to keep them of the ground, and the fruit clean and handy to pick when ripe. I am sure when the culture is better understood they will become as popular in the garden as Currants and Gooseberries. The large black fruit is useful in many ways, as for wine, jelly, and jam, also for mixing with Apples for tarts or puddings. The wine is highly recommended for sore throat.—G. C., Warwick.

MANNERS AND CUSTOMS—A CATALOGUE COMMENTARY.

(Continued from page 560.)

Général Jacqueminot (Rousselet, 1853).—Good, but rather slender growth and foliage; liable to mildew, but not much injured by rain; very free flowering, and a good autumnal, but decidedly thin; must be grown very strong and cut very young to be fit for show, but is exhibited fairly sometimes, and indeed has once taken the silver medal at the metropolitan N.R.S. Show as the best H.P. As bright as Duke of Edinburgh when grown to perfection, but not lasting or large; still this good old Rose knows its weakness, "pulls itself together" in hot weather, and tightens its point as hard as it can. Is the great grandfather of almost all our red H.P.'s, and is still, I believe, grown very largely for market and florists' purposes, "Général's" being almost as well and affectionately known in the trade as "Niels."

Gloire de Margottin (Margottin, 1887) is a new Rose, on whose manners and customs it is as yet too early to dogmatise, and I only mention it because it seems as likely as any to supersede "The General" last mentioned. I do not know its parentage, but in general outward appearance it is very much like *Gloire de Rosomenes* (Vibert; the date appears to be lost in the mists of antiquity), which is, I believe, the progenitor of *Général Jacqueminot*, and of most of our red H.P.'s. *Gloire de Margottin* is, however, though still thin, very much fuller, and seems at present to "take the cake" as the brightest of all known red Roses. A long grower and free bloomer. If it will force well and hold its colour it seems likely to run "The Général" hard.

Other "Glories."—De Bourg la Reine, very bright; De Ducher, rather rough; De Vitry did badly with me. Of Waltham and of Cheshunt, pillar Roses, do not seem to call for special mention. *Gloire Lyonnaise* (1884) was said to be a yellow H.P., but I could not make it anything but white, and small but pretty as a bud.

Grand Mogul (W. Paul, 1887), though a new Rose, has been fairly tried by me, and I consider it to be identical with Jean Soupert, but, as compared with all other Roses, to have quite distinct manners and customs. The foliage is fair, and the growth good but peculiar. One or two shoots run away considerably above the others, and give promise of good blooms, and when the bud forms at last it is of very good typical shape, and seldom comes cracked or divided; but now, when you expect the plant to put all the strength into the bud, it does not seem to do so; the stem thickens considerably at the base, and tempting plump wood buds for budding form all up the stem, but the flower buds swell very little, although it opens slowly. The bloom is much smaller and weaker than one would expect from the size of the shoot, though sometimes of fair average size, and the shape is undeniably good; a round smooth button in the centre, the other perfectly imbricated, and the outline regular. The bloom is not very lasting, the colour rather dull, and it cannot be called a free bloomer, or be reckoned among the best autumnals. Decidedly liable to mildew, which sometimes affects the petals, but not much injured by rain. A seedling from A. K. Williams, and it is strange that in all characteristics it should be so very similar to Jean Soupert, a Rose older than its parent; but perhaps if we knew something more of the actual pedigree of our principal Roses for two or three generations some of these likenesses might be cleared up.

Harrison Weir (Turner, 1879).—A weak grower, suitable only for show purposes. Only one stem should be allowed to a plant, and if grown in this fashion good growth and foliage may be obtained the first year after budding. Not very liable to mildew, or to be spoilt by rain. A grand bloom, coming pretty true, stout in petal, globular in shape, a trifle weak in centre, but of beautiful velvety colour and fragrant scent. Of full size when grown strong, and good lasting qualities; but a Rose of weak constitution, of no use as a free bloomer or autumnal.

Heinrich Schultze (Bennett, 1882) was a most useful introduction. Capital strong growth, with fine foliage, an early and free bloomer and good autumnal. Not very liable to mildew or to be injured by rain. The flower has large handsome petals, and is generally of a good shape when young, but soon falls abroad. An excellent hardy showy Rose of beautiful fresh colour and quite a large size.

Her Majesty (Bennett, 1886).—A well named Rose. We all know

the fable of the lioness, the queen of beasts, who, on being taunted with having only one young one at a birth (which is not true, by-the-by), said it was so, but that one was a lion. We acknowledge the imperial claims of Her Majesty, and that when a bloom does come it is often a queen; but will she not graciously concede that an average of only one bloom to four plants (which is what I had this year) is being a little too sparing of her favours? Manners and customs are notoriously strict and exacting in royal circles, and in this remarkable Rose we certainly have some striking peculiarities. Growth long, strong, and robust if well fed, but neither free nor (with me) rapid; makes extraordinary growth under favourable conditions, but a poor show if not treated regally and favoured with queen's weather. Prune high or low you will not get more than one or two shoots to a plant, and if the single growth of a maiden shoot be stopped, instead of breaking in several places like the vulgar herd, Her Majesty slowly shoots again from the top bud left, and continues one stem upwards as before. We may place the plants very close together, for the stems of each are few in number, and upright and stiff. Fine foliage and very large stems, terribly subject to mildew. A large proportion of the blooms come good, and are not much susceptible to damage by rain. They have grand stout petals, and are wonderfully full in the centre, so much so that the Rose has quite two shapes, and the best one was not known for the first year or two; for it has in the first stage a grand globular form, and when expanded and overblown it is yet so perfectly full, even when as flat as a pancake, as to show no eye, and be still presentable and wonderful though not so beautiful as a Rose. The colour is best and purest in the first of these stages; in the second it is something like that of a gigantic Marie Cointet. In size and lasting qualities it is quite at the top of the tree; as a free bloomer and autumnal absolutely at the bottom. I have not had the good fortune to see a single secondary or true autumnal bloom yet; but it does bloom as a maiden though not for certain, otherwise its title to the term Perpetual might well be yet in abeyance. Not the least remarkable point about this Rose is its parentage. It is said to be a seedling from the old Tea Canary, a yellow flimsy thing according to modern notions, and Mabel Morrison, a white sport from Baronne de Rothschild, particularly open and deficient in the centre. One would think that Mr. Bennett, on beholding the illustrious progeny of this apparently ill assorted pair, would be inclined to consider chance still as likely to be successful as the careful choosing of seed-parents; but he has, no doubt, his ideas and plans upon the subject, and fresh novelties in store, I hope, for expectant rosarians.

Henri Ledechaux (Ledechaux, 1868) and *Hippolyte Jamain* (Lacharme, 1874) are both members of the Comtesse d'Oxford, or rather Victor Verdier family, all of which have the same general manners and customs, which it will not be necessary to repeat again. Fairly good growth, with smooth characteristic wood, the first shoots losing their foliage early; objecting strongly to light soil or the Manetti stock; free producers in summer and autumn of blooms of good globular pointed shapes, but not very lasting. Of the two here mentioned the former is very thin and not suitable for exhibition, but has a charming bright bud for buttonholes; and the other is early, large, and a capital autumnal, but requires a rich soil.

Horace Vernet (Guillot, 1866).—A typical show Rose; grand in the exhibition box, few surpassing it; but to be sedulously avoided by those who grow Roses for ordinary garden purposes. The plant is of a thoroughly weak constitution, and cannot be kept in health and strength beyond a year or two. Indeed it is almost useless as a cut-back; no other Rose is more worthy of the annual system of culture—budding afresh on strong stocks every year, and doing away with the old plants—and for none is it more necessary. When thus treated the growth and foliage are good enough, one would think, to keep the stock roots in health; but the plant is sure to dwindle, if preserved. Not very liable to mildew or much injured by rain. The blooms generally come good, and good they are, with noble stout petals, well filled centre, perfect shape (pointed, passing to imbricated), good dark colour, and lasting qualities of the first order. Not a free bloomer nor a good autumnal; these are 'lions' to be made much of, and we must not expect many of them. Cut away the plant, as soon as it has bloomed, with a ruthless hand, to get the biggest and best buds for propagating. Waste none on weak stocks, and bud a good many, not delayed too long, for some may fail and require rebudding; and, whether you keep the old plants or not, you will not cut from them so long as you have young plants to go to. Hundreds of gardeners and rosarians, who would otherwise never have heard of the great French artist, have had his name "familiar in their mouths as household words," by the help of this noble Rose his namesake.

Jean Liabaud (Liabaud, 1875).—Fair growth and foliage, not very liable to mildew or to be much injured by rain. Not a very free bloomer, a poor autumnal, and a Rose of shocking manners. Occasionally one gets a lovely bloom, of open imbricated shape, not strong in the centre, very dark and shaded in the most beautiful way with brighter tints. But if you get one such in the course of a year from a dozen plants, you will be pretty lucky. An amateur, with not much room to spare, will probably soon have had enough of this Rose.

Jean Soupert (Lacharme, 1875).—See Grand Mogul.

John Hopper (Ward, 1862).—A very popular and well-known English Rose, raised in the eastern counties. Very hardy, with strong growth and good foliage, liable to mildew, but not much injured by rain. The blooms come early and of fairly regular form, but the shape is open, and not of the first class. The colour is beautifully fresh at first, but this is

even more fleeting than the shape. Not of the largest size, but a free bloomer and a good autumnal. This is everybody's Rose, of strong constitution, doing well as a cutting, or on poorish soil.

John Stuart Mill (Turner, 1874?).—Of strong, long, growth and good foliage, not very liable to mildew or to be injured by rain. The National Rose Society's catalogue describes this as "a good reliable flower;" but it is not so with me. It is true, more or less, of a great many Roses that they come well in some seasons but not in others. The one under notice has been very uncertain with me generally, but came exceptionally well and good last year. A capital imbricated red Rose, of average size and good lasting qualities, but only fair in freedom of bloom or as an autumnal.

Jules Margottin (Margottin, 1853).—Of strong hardy growth and good foliage, not liable to mildew or to be injured by rain. A very free bloomer and good autumnal, but a poorly shaped rough bloom from a florist's point of view. Early, sweet-scented, and not particular as to soil or treatment. A useful old-fashioned garden Rose, of strong constitution, and suitable for cottage gardens or odd corners. The seed parent of Edward Morren.—W. R. RAILLEM.

(To be continued.)

TEA ROSES IN A COOL CONSERVATORY AT CHRISTMAS.

TEA Roses are welcome blooms at all times, but at none other more so than Christmastide, when the demand for cut flowers generally quite keeps pace with the supply. At that season their chaste beauty is a pleasing relief after the Chrysanthemums, and always finds ready appreciation. In those establishments where houses are specially used for forcing flowers it is no very difficult task to have them in quantities at that time, but in gardens of more limited extent with scanty appliances this is not such an easy matter. Any method that will assist the supply is readily turned to account for that purpose in the latter places. For several years past we have been able to cut good quantities of blooms about Christmas from a plant which covers a portion of the roof of a cool conservatory without subjecting it to any special treatment, which might prove injurious to the other plants. In fact the management which it appears to like has been more beneficial than otherwise to them, although they are of the ordinary character for such a structure.

The plant itself is worked on the Briar stock, which I have always found the most satisfactory for Tea Roses, and planted in a narrow border on the shady side of the house. The compost in which it is planted is a sandy loam well incorporated with brickbats and a scattering of crushed bones, placed over a thick layer of rubble for drainage. But I may here mention that in my opinion a wonderful mixture of ingredients, which some consider indispensable, is less necessary than a simple compound which will remain sweet and porous for a long period. When planted in a compost of this description the necessary food for its continued prosperity can be readily supplied when necessary. In our case all that is given in that way is an occasional watering with liquid manure when the family are away, and a sprinkling of artificial manure when the former cannot be applied, but not oftener than twice in the course of a year.

It has been said that the abuse of the waterpot has killed thousands of plants, and if this be so it may be added that the wrong use of ventilators is accountable for the death of tens of thousands. At all stages careful ventilation is of the utmost importance for the welfare of Roses, direct currents of air on the tender growths being most disastrous in the results. Even if the thermometer registers 10° or 12° more than the orthodox number when an easterly wind is blowing the occupants of the house will show that they have had quite enough of it through the laps of the glass, without letting it into them full face, at least we have found it to be so, and if the Journal has been read aright this is no solitary experience. Another matter which we have attended to is keeping the growths well thinned, cutting weakly shoots clear away, encouraging only the strongest, and those well apart, more flowers and better being got from this treatment than when they are allowed to grow into a thicket. By following this course of management an almost continuous supply of blooms can be had from one plant, but if a quantity is required at any special time an extra thinning ought to be done about three months beforehand. Such a pruning was given to the plant in question at the latter end of September, and now for several weeks we have been able to cut fair quantities from it, a good average sample of which is forwarded for the Editor's inspection, besides an occasional bloom ever since.—M. D.

[The blooms received were of great excellence, and accompanied with large, deep green, glossy leaves. The variety was Adam.]

ROSA LAXA.

GARDENING papers are recommending, on the authority of Otto Froebel, Zurich, Rosa laxa for standard Roses. Is Rosa laxa to be found in English woods or hedges? I should like to get some, and seed to sow for Briar seedlings.—ROSA (MONO-MANIACA).

THE TREE TOMATO.

At a recent meeting of the Royal Horticultural Society's Fruit Committee the Rev. W. Wilks, Shirley, sent fruits of the "Tree Tomato" *Cyphomandra betacea*. They were acutely egg-shaped, 3 inches long and 1½ inch in diameter in the widest part, dark

salmon in colour, firm, sprightly and agreeable, and possessing a brisk Tomato flavour. A cultural commendation was unanimously awarded, accompanied with a request that plants be grown at Chiswick. Mr. Wilks sent the following description of the plant with his exhibit:—The "tree" on which the fruits shown have been grown is about 9 feet high, with a spreading much-branched head. The leaves when young are of a violet purple colour, changing with growth into a deep green. They are very large when fully developed. The blossom is precisely like a *Solanum*, being, in fact, to an ordinary observer identical with that of the plant commonly known as "Black" or "Woody Nightshade." It is an abundant bearer, the fruit ripening late in November and throughout December and January. The fruit when raw has a much firmer flesh than a Tomato, and is slightly more acid, but when cooked it is almost indistinguishable from the ordinary Tomato. The plant has been grown throughout in a cool orchard house, from which only frost is excluded.

Cyphomandra betacea is a member of the *Solanum* family, and in

FIG. 3.—THE TREE TOMATO, *CYPHOMANDRA BETACEA*.

Decandolle's "Prodromus" about thirty species were described, chiefly from South America. The Tree Tomato has been known to botanists for many years, and has been cultivated in botanic gardens for a considerable time, but it is rarely seen in private gardens. As it succeeds in a cool house and is easily grown it is worth a trial as a fruit-yielding plant, and is very ornamental when its bright red fruits are ripe.

EUCHARIS GRANDIFLORA.

I HAVE read with interest from time to time the articles on the above plant; and now send you a few notes as to the system adopted here. In the middle of a house which is devoted to Palms, Ferns, &c., there is a small rockery, which was at one time planted with Ferns. Finding the latter did not thrive well, being so far from the glass (about 10 feet), I thought I would try a few *Eucharises* in it. The bulbs were placed between the stones, the only soil used being refuse from the potting bench. They have now been planted ten years, and with the exception of the top soil being scraped off in the spring and a top-dressing of loam and manure and a little liquid at flowering time they have had nothing else. Along the top of the rockery is a shelf filled with Palms, and nearer the roof two more shelves with smaller plants. The *Eucharises* get the drip from these, so that the drying-off process is not rigidly followed here. We nearly always have some flowers, but regularly three times every year. They flowered last September, and they are now in full flower again. I enclose a spike and a leaf, asking your opinion as to whether it shows any signs of "mite." Some of my

friends would be disposed to think there is.—JNO. SHORT, *Hummers-knott, Darlington.*

[The plants appear to be in most vigorous health, and we can certainly see no sign of the mite. The largest leaf blade is 18 inches long by 7½ inches broad, the leafstalk 13 inches long. The strongest flower scape is 30 inches long, bearing five flowers. All the leaves are of great substance and a fine deep green colour. Flowers of "a cross between *Mastersi* and *candida*" were sent, but they were too withered to determine their characters; the corona seemed to be much reduced.]

THE BLACK MAZZARD CHERRY TREE.

THE Wild English Cherry tree is a frequent object in the landscapes of the older settled portions of the Middle Atlantic States, and, especially when in bloom, it presents a most dignified and attractive appearance. We know a tree about 50 feet in height, and of massive form. In bloom it is literally a sheet of white. Botanists call this species of Cherry *Cerasus Avium*, or, following Linnæus, *Prunus Avium*; horticulturally it is known as the Mazzard. There are two varieties of it, bearing respectively black and dark red fruit; the black variety is the one most one most disseminated. The fruit, which is bitter before maturity, retains but little of this taste when ripe, but becomes sweet and pleasant, and is eaten greedily by the birds. It has been extensively used in making bounce, or Cherry brandy, and the seeds are planted by nurserymen, as the young trees are the favourite stocks on which to bud and graft the choice cultivated varieties of Cherries. This species of Cherries and its varieties are called *Merisiers* by the French. Loudon, in his "Encyclopedia of Gardening," says: "The *Merisiers* are like the wild Cherries of the woods. The fruit is small, with little flesh, which contains, even in its fullest maturity, enough of bitterness to justify the name of *Merise*; formed, as it is said to be, from the words *amere* and *cerise*. From this appellation has probably arisen that of *Merries*, which is given to wild Cherries in many parts of England." The word *mazzard* has undoubtedly the same origin. "Were Cherry trees scarce, and with much difficulty propagated," remarks Hanbury, "every man, though possessed of a single one only, would look upon it as a treasure. For besides the charming appearance these trees have, when besnowed, as it were, all over with bloom in the spring, can any tree in the vegetable tribe be conceived more beautiful, striking, and grand than a well grown and healthy Cherry tree, at that period when the fruit is ripe?" Alfred Smee, the author of "My Garden," says, in that work, in mentioning fruit trees that are used as forest trees in England:—"The Wild Cherry tree is extremely beautiful when covered with its white flowers, and in autumn its scarlet leaves render it again very attractive." The last named characteristic is also noticed by French writers, who put it forward as one of the attractions of the tree. Our own writers have not so particularly recognised this feature, though no doubt deserving, as our more highly coloured Maples, and Liquidambars, and other trees are still brighter in their autumn tints.

Wilson, in his "Rural Cyclopædia," says the fruit of this Cherry is "at present one of the most popular in the London market." It used to be sent to market from this region, but for the last twenty years but little has been seen of it. The author last named says that three sub-varieties of the species are cultivated in certain counties of England, under the names of the Bud, the Small Black, and the Honey; and the fruit of the last of these is "very small, pale red, and remarkably sweet, and is largely used for making Cherry wine." The black variety has always been the popular one in this country.—(*Vick's Magazine.*)

SALVIA SPLENDENS.

THIS, among the family of the Sages, is well worthy of the title of splendid. Rivals in the same family group it may have in summer and autumn, but in the earlier winter months it is unmatched. Contrasted at this season even with the loveliest and the gayest of other flowers, it constitutes one of the most dazzling ornaments of the greenhouse or conservatory. Even where there is nothing else very striking beside it, its own elegant foliage sets off to advantage its rich racemes of scarlet flowers. This interest is prolonged from the calyx being of the same colour as the corolla, as it is first expanded, and remains for some time after the corolla has dropped.

Salvia splendens, as well as most of our greenhouse and bedding-out species, is a native of Mexico. The term *Salvia* is derived from *salvus* (safe), in allusion to the beneficial character of many of the species in a medicinal and culinary point of view. Even now, many who are not yet decided epicures may be looking forward to the festive period, and thinking of partaking along with friends of those good things in the preparation of which even the common Sage is brought into abundant requisition. At the present time the plants, if safely lodged in the greenhouse and conservatory, should not be exposed to keen draughts of air if it is wished to preserve the bloom as long as possible. In watering, let the liquid be a little warmer than the air of the house, and if coloured with guano, superphosphate of lime, &c., they will like it all the better. If it is not convenient to have manure water, much the same object will be gained by top-dressing with old dried cow or sheep dung. Watering over it will enrich the compost, and, acting also as a mulching, less watering will be necessary, which is something, as if the pots are crammed with roots, and the weather should be fine, they will drink like any topers. They will bloom well either in small or

large pots, though for striking effect large plants in large pots are the most desirable. "All very well!" say some dozen friends of ours at once, "I should like to have half a dozen of these fine large plants in my greenhouse now, they would look so well among *Chrysanthemums* and opening *Camellias*, &c.; and I should like a few small plants to enliven my window, but then I have always been deterred from growing them from the great space they would occupy when they have flowered, or before they had commenced to bloom, and then numbers of clever people have dunned into my ears to beware of them as I would shun the plague, as a few plants would soon fill a whole house with red spiders, and then farewell to all my other favourites, so far as their healthy looks are concerned." Now, even in these days of cheap glass we are well aware that from various causes the husbanding of space under glass is as much demanded as ever. But, even in this respect, our friends the *Salvias* are wonderfully accommodating. They are but little subject to the spider when sturdily, not daintily, reared. In any circumstances they are less troubled with it now than during the dog days. A slight syringe over the leaves when in bloom—and in cold weather, when a little heat is necessary, the brushing over the pipes or flue, when not very hot, with flowers of sulphur and water—will be next to effectual in keeping the intruder away. So much for present management.

Now, as to preparing for another year. As soon as the plants have done flowering, give away, or transfer them all save one to the rubbish heap; place the one saved in any out-of-the-way corner where a stray ray of light may reach it, and where frost cannot visit it—under the stage will answer well enough. There the leaves will soon drop, but never mind, though, if a few small ones remained on the points of the shoots, just to keep the sap in motion, it would be as well; yet, if you manage to keep the stems alive it is a matter of no great consequence, as from them plenty of young shoots will break in March or April, and if there are few or no leaves on them during the remainder of the winter you will not be troubled with nightmare about the red spider, as the stems will be too tough food for them. In the end of March, or the beginning of April, take off rather more short stubby shoots than you will want for plants, as some may fail; cut them across below a joint, insert them in cutting pots half filled with drainage, the other half with light sandy soil, with the exception of half an inch at the top, which is to consist of sand alone. If you have nothing but a greenhouse, the cuttings should be placed under a bellglass, or if inserted in a small pot, and that again placed at the bottom of a larger one and a square of glass placed over its mouth, it will answer admirably. This is to prevent the juices of the cutting being evaporated, and, farther to effect this, shading must be resorted to in bright weather. The number and size of the leaves to be retained must depend upon the means you possess of preventing the transpiration of the juices of the cuttings. They may thus be struck in a window or greenhouse, but a Cucumber box is the very place for them, and if there you can give them a shady warm corner, and the bellglass, or the square of glass in addition, you will be surprised to find how soon your cuttings will be changed into rooted plants.

If you have nothing but the greenhouse and a cold pit, shift the plants first into 3-inch pots, and then successively into 6 and 12-inch pots, setting them as soon as possible in the pit, as there you may keep them close for a time to encourage rooting after each shifting. But if you can command a little bottom heat, such as the side of a Cucumber box, shift at once into 6-inch pots, and then again into 12's. In either case set them out of doors by the middle or end of June, either upon coal ashes or plunging the pot in a border with a tile at the bottom of the pots to prevent worms entering, and to prevent the roots going out, shade in sunshine when first turned out, stop every shoot to make the plants stubby and bushy until the middle of July, water with weak liquid manure and clear water alternately; frequently after a rainy day syringe the whole of the foliage well with a weak, clear solution of soot and water; provide them with a temporary shelter by means of mats or waterproofed calico by the middle of September to guard against heavy rains, storms, and frosts, and set them in the house by the end of October, or rather, if convenient, by the middle of the month, and the blaze of scarlet in November will well repay all your efforts. Many with a keen relish for floral loveliness cannot afford to get costly plants, and this is just one of the things for them, as the cost will almost entirely consist in their time and labour. For getting fine little plants for the window, it will be time enough to strike the cuttings in June. Three things in growing these must be attended to. Syringe the plants frequently, water liberally, and prevent frost ever affecting the foliage. Equal portions of loam and peat will suit them well; a little dung added to the last shifting will be advantageous.—R.

THE ADVANTAGES OF FIRM SOIL.

THE advantage of firm soil is not sufficiently recognised, but it is one of the greatest aids to successful culture with which I am acquainted. The benefits are confined to no class of plants, but apply to kitchen garden crops, plants in pots, Vine and fruit tree borders of every description. Many, however, do not try to make the soil firm. In potting it is not always pushed or rammed down firm. It is generally shaken about the roots and pressed with the fingers and thumbs, but this is not always sufficient. Indeed, I have known some in potting to leave the soil loose that the "roots might penetrate it freely," and they might do so by rambling through it and becoming long and fibreless, but it is close matted fibry roots that are the most satisfactory, and

these are only produced in firm soil. The leading roots have to fight their way through a firm soil, and this causes them to throw out innumerable fibres which are the life of the plant.

Loosely potted plants are constantly requiring water, as that which is given passes through quickly, and if the drainage becomes at all clogged the whole soil is soon a miniature bog, and failure immediately follows; but this never occurs with firmly potted plants. The more difficult the plant is to grow the firmer the soil should be made, and many understand this, as we all know how very firm good cultivators of Heaths, Azaleas, and some other hardwooded plants pot their specimens. The result of potting a Heath loosely can be readily imagined, and the disastrous consequences are to be found in other plants as well, only perhaps they do not show it so soon or so conspicuously.

It would be impossible to calculate the number of plants annually killed or kept in permanent bad health by loose potting, and the remedy is in the hands of all. Give Vines a loose border, and they will produce long jointed wood, flabby leaves, and straggling bunches, but in a firm border all these are reversed, and the firmness of the border is shown in the sturdy development. Many who try to improve their straggling Vines by adding rich top-dressings would accomplish the work much sooner and better if they simply trod the surface down a hundred times. I know Peach and other wall trees that are sometimes disturbed by moles burying amongst the roots and loosening the soil, and these are never in such good health or so fruitful as others that have the soil firmly pressed about the roots. In fact, fruit trees show the disadvantage of having to exist in a loose soil as much as a plant in a 6-inch pot, and it is impossible to make fruit borders too firm.

Cucumbers and Tomatoes may be grown capitally in a hat box full of soil if it is firm, but in a loose heap they only produce soft unfruitful wood, and always seem to be hanging between life and death. It is a difficult matter to prevent Pine Apple plants assuming a yellow hue when they are potted without the soil being rammed, and firmly potted plants of all descriptions bear much more cold and damp in winter than those in loose soil. It is a grave mistake to allow the ground to remain loose that the water may pass through and away from it freely, because it does not do so, but retains the moisture far more than the firm soil.

Vegetable crops are greatly influenced by firm soil. In the case of Onions, Turnips, and Beetroot the loose soil will cause them to grow deformed, forked, and small, but firm soil induces them to "bulb" early of splendid form and a great size. Carrots and Parsnips, too, show the difference, as forked roots are the rule in loose soil, whereas in firm material they are straight, clean, and perfect. During the last ten years I can safely say we have not lost a score of Celery plants through "bolting," and I attribute their immunity from this common complaint to the thorough treading the soil receives round the plants. Extremes of drought and wet do not affect vegetation half so much in a firm soil as in a loose one, and in short wherever the production of high class crops is desired firm soil should be provided.—J. MUIR, *Margam Park, South Wales.*

THE CAGED BULLFINCH.

If the good qualities of the bullfinch were generally known it would be more frequently sought as a domestic pet. For at least twenty-five years I have never been without one, and I can testify they are amusing and affectionate birds. Of course, the song of our English bullfinch is not to be compared with that of some other finches; it consists but of few notes, yet it has an agreeable wildness about it, and as the bullfinch is somewhat imitative it often picks up and mingles with its natural song fragments of vocal or instrumental music it may have heard. When young it may be got to learn any tune that is assiduously whistled to it daily, and it is stated that the bullfinch can be taught to utter short words, but I have never had proof of this. Towards those who feed it, and others it frequently sees, this bird soon shows affection, jealousy also of notice given to other birds, or even to children. It has a terror of cats which is almost ludicrous, but, on the other hand, it shows little alarm of some things which much startle canaries, such as an unusual head dress, or any peculiar noise. Bechstein states that the bullfinch seldom lives long in confinement—from six to eight years, frequently less. I have had them live ten, and I believe mismanagement or neglect is the cause by some persons soon lose bullfinches. Should they be fed with seeds, not paste, they require hemp mixed with canary, but the hemp should be crushed. I do not think rape is good for them, for they seem to be benefited by a little maw or poppy seed occasionally. Green food is very important, to be varied according to the season; they are fond of Plantain, Groundsel, Shepherd's Purse, and Watercress. As their feet are apt to be clogged these must be looked after, and now and then washed.—NATURALIST.

BOTANY IN AMERICA.

THE great botanical establishment which the people of New York are still talking about vaguely is to be realised in St. Louis. It is provided for under the will of Mr. Henry Shaw, who died during the past summer, having for many years devoted his leisure and a considerable part of his income to the establishment and care of a public garden in his adopted city. The whole of his estate, with the exception of a few small legacies, is now left to a board of trustees for the benefit of this garden. It has been appraised at nearly 3,000,000 dollars, and produces a net income of about 50,000 dollars; but as a large part

of Mr. Shaw's property is invested in unimproved real estate within the city limits of St. Louis, the income of his estate may be expected to increase enormously with the growth of that city; and Professor William Trelease, the newly appointed director, will, in all probability, soon find himself at the head of a better endowed establishment than any other of its kind which has ever existed. There is no botanical garden in the world, with the exception of that at Kew, where the annual expenditures are not far from 100,000 dollars, which enjoys an income of anything like 50,000 dollars, and a vast amount of good and useful work can be accomplished every year with that sum of money. Professor Trelease, with the income now at his command or which will be available for his purpose in a short time, will be able to lay the foundation of an establishment of such scope that it will soon make St. Louis the botanical centre of the New World and draw to it students from every quarter of the globe. His early efforts, very properly, will be devoted to elucidating the botany of North America; and he is fortunate in possessing as a nucleus of the St. Louis herbarium the collections of Engelmann, which, in certain groups of plants, are so inestimable value.

Of special interest to young men who desire to become gardeners is the plan, not yet entirely matured, of offering, in connection with the Shaw Garden, six scholarships for garden pupils, for the benefit of young men between fourteen and twenty years of age, who are to be taken for six years, and who will be expected to work in the different departments of the garden, receiving, besides, theoretical instruction in botany, horticulture, economic entomology, and as much land surveying and book-keeping as is necessary for a gardener having the charge of a large estate. It is proposed by means of these scholarships to make gardeners, and not botanists, and a taste for the manual work of the garden will be insisted on in the young men who hold them. They will receive pay for their work, and be given, free of cost, plain and comfortable lodgings near the garden, as well as free tuition in the School of Botany of Washington University, and such other instruction as may be necessary. Never before has such a chance been offered in this country to young men desiring to become thoroughly educated and trained gardeners, and the influence which Mr. Shaw's munificent bequest will exert through these scholarships upon horticulture in the United States can hardly fail to be great and lasting.

The trustees of the Shaw Garden have it in their power to build up a great and useful institution of science and learning. Their opportunity is magnificent, and their responsibility is correspondingly great.—(*American Garden.*)

FRUIT FORCING.

VINES.—*Earliest Forced.*—Great care is required at this time to avoid chills, such as those resulting from cold currents of air and drenching the borders with cold water. Now the foliage is increasing root action will be excited, and should be encouraged by supplying tepid water at a temperature not exceeding 90°, not allowing the fermenting materials to decline in heat at this critical stage. It is a good plan to keep a heap of leaves and stable manure in reserve, from which the supply may be drawn as required. Disbud and tie the shoots down before they touch the glass, not being in too great a hurry in stopping nor restricting to a certain number of joints beyond the bunch, yet there ought to be two, and better three or four; but extend the growth so as to insure plenty of well-developed foliage, yet avoid overcrowding. Remove superfluous bunches as soon as choice can be made of the best, avoiding overcropping. Keep the house at 70° to 75° by artificial means as the flowers open, and maintain a rather drier condition of the atmosphere. As soon as the fruit is set Vines in pots may be copiously supplied with liquid manure, maintaining a moist atmosphere. Damp the paths two or three times a day, and occasionally with liquid manure, keeping the evaporation troughs charged with the same.

Houses to Afford Ripe Grapes in June.—The Vines that are to supply these should be started at once, abundance of fermenting materials being placed on the outside border; or if it be already protected with a good thickness of dry fern or litter fermenting materials may be dispensed with, and if wooden shutters or glazed lights are at command for throwing off the rain it will be an advantage. Supply the inside border thoroughly with water at a temperature of 90°, and economise fuel by the free use of fermenting materials inside the house. Damp the house and Vines two or three times a day when the weather is bright, but in dull weather once or at most twice a day will be ample. The temperature should be 50° to 55° by artificial means, and 65° from sun heat.

Houses in which the Grapes have been Cut.—Prune the Vines with as little delay as possible. This will cause the spurs in course of time to become long; and so they do by any mode, but it is easy to train up young canes for their displacement. Strip off all loose bark, no attempt at scraping being made, and wash the Vines with soft soap and water. Avoid pigments, which leave a deposit on the Vines. Remove the surface soil or mulching down to the roots, and supply fresh material. Keep the house cool, but if utilised for plants the temperature arti-

ficially must not exceed 45°; indeed, plants that require safety from frost only should be placed in vineries when the Vines are at rest.

Late Houses.—Maintain a mean temperature of 45° with a dry atmosphere in houses in which Grapes are hanging. Examine every bunch frequently, and remove all decayed berries. Ventilate the house on fine dry mornings, and keep it closed when the weather is damp. Where late Grapes were ripened comparatively early, and it is desired to start the Vines soon after the middle of February, the Grapes may be cut, the ends of the stems being inserted in bottles of rain water secured in an inclined position, so as to admit of the fruit hanging clear of the bottles. Any dry room will be a suitable place where an equable temperature of 40° to 45° is maintained. This will admit of the Vines being pruned and the house cleaned.

KITCHEN GARDEN.

DIGGING.—Now that we have passed what is commonly termed the “turn of the year” work in the kitchen garden will increase weekly; it is therefore necessary that all who wish to have early crops and quick profitable returns must be prepared to plant and sow when opportunity offers. This can rarely be done to advantage when the ground has to be dug at the time of putting in the crops, but when manured and prepared before cropping is easy and expeditious work. Vacant quarters are now more general than they were a month or two ago, and all intended for early crops should be prepared at once.

PEAS AND BROAD BEANS.—Those sown some weeks ago are now through the soil. Sift some coal ashes very fine, and put a line of them along each side of the plants; this will prevent snails destroying the young plants. If in a windy or exposed position a mound of earth about 6 inches high can be drawn up outside the ashes, which will leave the plants in a sheltered furrow, and prove more beneficial than twigs or stakes, which are apt to “draw” them too much up. January sown Peas and Broad Beans are always good crops with us, and more of the early varieties should be sown on the first favourable opportunity. In a rich well-drained soil there is no danger of failure.

EARLY CARROTS.—For some years we made up a hotbed early in January, placed a frame or frames on the top of it, filled them partially with soil, and sowed the early Carrots, but we found the exposed manure acted like a sponge, absorbed the wet, and soon cooled to such an extent that it was no stimulant to the Carrots. We now use a frame 4 to 5 feet high at the back, and about 3 feet in front. The manure is packed firmly inside, and the soil is placed on this; the whole is protected, and the soil retains the heat double the length of time of the other way, and it is less littery. Only the Horn varieties should be forced, and 10 inches of soil is sufficient for them. This should be rather light and sandy, and contain a good sprinkling of soot. The manure must be trodden firmly down first, and the soil equally so on the top. If only 4 inches or 5 inches from the lights when finished that will be sufficient, as by the time the tops have gained size the manure will have subsided a little. The seed should not be covered more than a quarter of an inch, and if watered immediately after sowing no more will be required till the plants are visible. Protect from frost, and admit a little air on fine days.

EARLY RADISHES.—These are easily produced from now onwards. They do not require the same substantial or lasting bed as the Carrots, and a slight hotbed with a frame on the top is sufficient. If grown for private use a one-light bed sown every ten days will yield a constant supply of roots. They are very tender and crisp when raised in frames early in the season, and never fail to please as salad.

PARSNIPS.—Before the winter is over the bulk of these decay very much at the crown, and sometimes it is difficult to preserve them. We have lifted and stored them in sand or ashes and kept them dry in a dark shed, and we are of opinion that they are as well left in the soil as treated in any of these ways. The crowns may become black and pulpy, but the greater length of the root will remain sound, and the flavour is far better preserved in the ground than by any storing process.

EARLY SEED POTATOES.—Unless with very special facilities we do not recommend Potato forcing to be commenced until February. Those planted in frames or pots at this time make very long stems, but the tubers do not grow equally rapid, and January planted Potatoes are never very productive. The seed tubers intended for planting in February should now, however, be taken in hand. Place strong healthy tubers in one layer as close as they will stand to each other growing end upwards in a shallow box, shake a little leaf soil or sand over them. Place them in a house or pit where the temperature is about 60°, and in the full light. This will induce them to produce strong shoots, which will be a great gain at planting time.

CELERY.—The frost and wet have caused much of this to become soft in the upper part of the stems, and some may be afraid of losing it, but that earthed up and under soil is less easily injured, and is rarely spoiled. We have tried lifting it and storing under cover, but if anything it kept worse in this way than in the ground. When the weather is dry clear all the protecting litter away from it to admit air, do not replace it unless frost prevail, also remove the decayed ends from the stems. If finely sifted ashes or sand is put round the collar of each plant and pressed firmly down it will arrest decay much more than loose materials. Celery that is soft and all spongy to the root does not keep so well as the heads that are solid throughout, and whether Celery keeps well or not depends a good deal on this point.

EARLY BRUSSELS SPROUTS.—Some growers like to see their Sprouts

button about midsummer, and they rear them under glass to have them early, but by midwinter these are not half so useful as the late ones that only begin to sprout in September. A few rows of the former with us cannot be sent to the kitchen now, but the latter are medium in size, exceedingly firm, and quite fresh.

THE BEE-KEEPER.

NOTES ON BEES.

CONDITION OF HIVES.

EVERYWHERE hives seem to be in excellent condition, and are a marked contrast to what they were in the autumn of 1888. The only drawback, as I stated some time since, is that many hives which were at the Heather have virgin queens; that would have been avoided had the bee-keepers depended only on their nuclei for next year's stocks.

With the absence of such extremely cold weather next spring as we had in that of 1888, and fine weather in July and August, there is a good prospect of having an abundant harvest of honey in 1890, which with strong hives and but two weeks' fine weather in either month will be certain.

It is worth repeating—Do not delay getting everything likely to be required ready for next summer, particularly for the Heather harvest. Lay the plans beforehand, and when the time comes put them into execution.

Every succeeding year there seem to be many recruits taking advantage of the Heather, and as many of the sites occupied by the bees are far from dwellings, there ought to be nothing to seek for; supers, packing cases, and all necessary tools for removing supers should be at hand. Nothing clears the supers of bees so rapidly and effectually as the carbolicised papers, first used by me and announced in this Journal, but subsequently claimed by many who were but novices in bee-keeping. I do not wish to encourage a superfluous number of appliances, as they are sometimes expensive, and not unfrequently of little use; but there is one which I would not be without, and I am careful to have my appliances serve more than one purpose.

A TRIPOD.

In conjunction with a Westing's patent chain pulley and a steelyard this weighs hives, supers, &c., with little trouble, and costs (complete) about 20s. or thereabouts. It also forms a manipulating tent, but of course requires a calico cover, costing about 7s. when finished. In addition to the uses mentioned it serves well for camping out either by night or by day. A spirit or mineral oil lamp does all that is necessary for heating or cooking. A packing box serves as table, bench, or seat. I do not know anything more useful where workmen are to take shelter from showers. Gardeners, for example, may have certain work to perform during an inclement time of showery weather. Basket making or other needful work could be carried on in one of these during the time the showers last, and then being kept dry the men are more comfortable and more work is performed than if they had to stand out the gales. The tripod is light and easily carried about from place to place, and is useful for transplanting trees and shrubs. One is easily made. A card, chain, or hoop of the proper dimensions are all that is necessary to hold the legs together. My own is made with a circular crossed piece of wood for the top with a bolt hook for suspension in the centre, the legs 2 by 1½ inch rounded on the top to form a hinge or knuckle; a piece of wire passes through the centre of the arc into kneed pieces of iron held firm by screws, as is also the pivot. It measures only 8 feet high, but when expanded has ample room for six or eight men to take shelter in, or for half that number to work.

It is actually folly to take bees to the Heather and leave them to chance, as many do, until the end of the season, unless when

they have been deprived of everything, and sent to the Heather to fill up from the foundation. This system gives new combs and honey of superior quality, but not so handy nor so saleable as when in supers. The best plan to accomplish that is to send the hives to the moors, with plenty of bees in large hives, in which the honey in the body boxes has been kept secure, but from which all supers wholly or partly filled have been removed, and bees numerous enough to take possession of them again. If any of them have a paucity of brood in the body of the hive, remove the empty combs and fill with those having plenty, and let this be done three or four weeks before the Heather may be expected to be in bloom. The older bees are, if not worn out, the better they work, but they are more vicious; bees under three weeks old do not attack people readily, and it may be safely said that bees three or four months old are better fitted to gather surplus honey than those at six weeks old. It is a common saying amongst bee-keepers that the vicious bees are always the best honey collectors. This is because of their age, and not of the variety, as old bee-keepers supposed when only one kind of bee was in the country.

Bees when at the Heather, except in specially fine weather, are apt to leave their supers and store the honey in the body of the hive. To prevent this overhaul the hive (I speak of the Stewarton or Lanarkshire hive), and if the brood frames can be got into two boxes do so, removing the under one for a time until the bees have taken to the supers, then at the earliest opportunity return the under box and combs, and then you will see them work in earnest. —A LANARKSHIRE BEE-KEEPER.

YOUNG BEES IN DECEMBER.

THANKING you for the answer inserted in the Journal respecting bees fanning, I am again taking the liberty of putting some other questions concerning bees. On December 19th I found a young bee dead on the landing board. The bee was of white colour, and on December 21st I found another dead, which appeared to be a few days older. I enclose the two, and perhaps you could then tell me whether there is any sign of foul brood, or if these have been chilled in the frost. Is it right for the bees to be breeding now? There is no smell from the hive, and since you answered my letter I have covered them well. I also enclose an old bee, and ask you whether it is an English black bee, or is it crossed with foreign blood? As the bees weighed 40 lbs. when brought to their new home, would they on account of young require feeding now or in February, or not at all? Is it mineral tar or gas tar you advise using for the hives, and should turpentine be mixed with it to dry it, and should the inside of a bar-frame hive be so dressed as well as the outside? I brought the bees to their new home the last week in October. —A YOUNG BEGINNER.

[The two immature bees are simply chilled, and there is no foul brood. When a hive is affected with foul brood the bees do not draw them from the cells, nor can they do so very well, because of the gluey and adhesive nature of the dead larvæ, not the pupa. There is a disease that the pupæ are attacked by and which the bees could remove; but from what I have seen the bees do not draw them from the cell when dead as they do when the young are chilled or deformed, the latter arising commonly from retarded development through cold.]

It is difficult, nay impossible, to tell the cross of any variety of bee from a single specimen, and very difficult to know accurately in many cases what they are from a whole swarm. The one sent is not a native black bee, nor is it a pure one of any breed. I should think it is half Carniolian, crossed with a black. The rudimentary yellow stripe, so prominent in the black bee, is almost absent in this one; then the thorax is quite black. This peculiarity in crosses is somewhat singular, appearing frequently in the first cross of the lightest-coloured varieties, and darker than any known breed. This dark colour on the thorax appears to be greatest change when crossing has been effected. The young bees in your hive seem to have been the cause of so much fanning of late, and with so mild a season as the present one has been there is nothing extraordinary in the case, as many bees commence breeding immediately after the shortest day. Carniolians seem less inclined to breed early than the yellow and Punic races do. I have a letter from a bee-keeper in the West Highlands who has an extensive apiary. He says, "I have to-day (December 16th) taken a quiet peep into one of my Carniolian hives, and find there are both eggs and larvæ in it, and this too when the thermometer stood at 20° Fahr." You, along with the rest of us, no doubt will have observed "A Hallamshire Bee-keeper's" opinion on bees hibernating. I am inclined to think he will be in a difficult position to explain how bees hibernate when they have been known to breed throughout the whole winter, and when the mercury was down at zero. The apparently dormant state bees show more or less throughout the whole year will require another name than hibernating. I suppose 40 lbs. is the gross weight of your hive. It will be well to feed as

early as the weather will permit in January, immediately after the bees have had an airing.

Gas tar is what I use for my hives, but it is the spirituous or thinner and finer sort, caught in the furthest removed interceptor from the retort; this dries quickly, and has a brilliant surface. I use it inside all my double-cased hives, but not inside the single-cased ones; but they would, I believe, be all the better for it. If common tar is used a little turpentine or naphtha is necessary to quicken the drying. Double-cased hives will be less useful in the future. —A LANARKSHIRE BEE-KEEPER.]

THE HALLAMSHIRE GLASS SECTIONS.

I SEE by the letter of "A Howdenshire Bee-keeper," page 564, that the editorial footnote to my article on page 519 is being interpreted in the way I thought it would be. I am asked, "Why I did not plainly tell of my intentions at first," meaning, I suppose, my intentions of taking out a patent on my invention. I think I shall best answer this question by explaining my motive and object in taking out a patent. Firstly, it was to secure the invention in such a manner that all bee-keepers could freely make and use it; secondly, to prevent others from making capital or getting credit for it; thirdly, to fix the date above question in view of any possible priority claim; and, fourthly, to have the power to take legal proceedings against anyone who tried to tamper with it. If I had not patented the invention, and had divulged the plan, there were plenty ready to take out patents for their own benefit; in fact the attempts to get the secret were many and curious.

When a man patents anything, the exact date, and, by implication, even the exact time also, is put down beyond question by anyone. The applicant states exactly in his own words and by means of his own drawings exactly what his own invention is. There is no restriction as to how many or how few words he may use or how many drawings he may send in, nor how intricate they may be. In my case I sent seventy-five illustrations on twenty-five foolscap sheets. These were the drawings alone. The Patent Office advertises all particulars in respect of it, and gives an abstract with a reduced copy of the drawings in the official weekly Journal, price 6d.; and they publish at a nominal price, and always keep in stock exact copies of the drawings with every word the patentee has had to say, for sale to anyone, and will send them post free to any part of the country for the amount of the postage extra. As a matter of fact and law a patent is the most public publication possible in this country, but how many know it?

When a man has his patent, it is a property for him to deal with just as he would with any other property; at least this was the law to the end of 1883. Now the law says he must grant licences to anyone to use his patent that likes; if terms cannot be agreed on between the patentee and user, the Courts have power to order a compulsory licence and to fix the terms, so that there is nothing to prevent a patentee granting free licences, or only charging a nominal price. I have said "a child can make my sections," but I have never said everyone would have a full legal right to make and use them; and if back numbers are referred to, it will be found that I have plainly hinted that I was going to take steps to prevent being deprived of the honour attaching to the invention.

The plain facts are these. I have a fairly large apiary of about thirty stocks, and some thirty extra empty hives of various patterns, which for years have been devoted to experimental purposes. I have never hesitated to put twenty stocks in experiment to try and solve any problem. Now to take upon myself the trouble and responsibility of protecting everyone who wants to use glass sections, to say nothing about the expense I have been at in my experiments solving the problem, is more than I feel justified in doing, but by making a small charge I hope to do all I want, so that the benefits will outweigh the annual charge. There is another matter I have under serious consideration—viz., I must either drop bees, or hire someone to help me to look after them, at least in the summer. This is what I want to do, then I can carry out very many experiments which is at present impossible. Hobbies are all right in their place, but when a man has to neglect other matters to ride his hobby, he must either curtail his riding or make it pay as part of his regular business.

I hope I have made the matter clear, and had hoped to see bee-keepers employing their spare moments making sections on their own hearths in winter instead of having to buy foreign ones. I shall keep the patent in force as long as possible, even if I do not get a shilling towards the £150 that will be required to do it.

Replying to "A Sussex Amateur" on page 541, I do not include him amongst those who have been trying to set up the priority claim; but as the sections have been illustrated, described, and discussed elsewhere, there is nothing really to discover even afresh. —A HALLAMSHIRE BEE-KEEPER.

[As we permit our correspondent to state where the drawings can be obtained in a complete form, there is not the least necessity for our publishing the eight which he supplied to us, nor can we insert any more explanations regarding this matter.]

TRADE CATALOGUES RECEIVED.

Webbs', Wordsley, Stourbridge.—*Spring Catalogue, 1890, Illustrated with Coloured Plates.*

 J. C. Wheeler & Son, Gloucester.—*Select Seed List for 1890.*

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Rosa laxa (*R. D. and others*).—We are not able to say whether the stocks referred to are grown for sale or not. If they are, and it is desired to distribute them, they will perhaps be advertised.

Double-spathed Richardia (*M. C., Brighton*).—The specimen you send is not novel to us. We have seen many similar, but do not remember a better example. These double-spathed specimens indicate that the plants are strong and have been well cultivated.

Vine Wood (*J. G.*).—The wood is not so well ripened as it should be, nor the buds so round, bold, and firm as we like to see them, though we have seen less satisfactory wood produce fairly good Grapes. Efforts should be made to secure better ripened wood another year.

Show Gooseberries and Currants (*Reader*).—If you read the paragraph on page 548 again you will find the varieties named that were the most frequently exhibited, and that is one of the best tests of their suitability for the purpose in question. Lee's Prolific and Black Champion are two good Black Currants for your purpose; and the true Raby Castle, often sold as Victoria, a good red variety, but the Red Cherry has larger berries, but shorter bunches. Wilmot's Large White Currant is one of the largest, but the White Dutch well grown is good for exhibition.

Preparing Tobacco Paper (*E. S.*).—Provided you can make sure that the ordinary tobacco juice sold in jars is free from any deleterious substance, there is no objection to your soaking brown paper therewith, and, when dried sufficiently, employing it for fumigating purposes. It is much the safest plan before using the paper for general purposes to try it on a small scale on plants with foliage liable to be damaged by fumigation, and if found satisfactory it can be used extensively.

Peach Buds Falling (*Z-ro*).—The cause of the buds falling, as indicated by the wood, is imperfect development of the organs of fructification. This arises mainly from a too free and extensive rooting area, the soil being too loose, and the roots consequently do not form fibres, the wood is not short-jointed or thoroughly solidified. We advise lifting the tree carefully a little in advance of the leaves falling, making the soil firmer, adding clay marl if procurable to the extent of a fourth finely divided, mixing it well with the soil, and if this cannot be effected add about a sixth of old mortar rubbish, firming the soil thoroughly under and over the roots. Judiciously practised lifting is a certain cure for ordinary Peach buds falling, but they may fall from defects of treatment, which we do not think have occurred in your case.

Tobacco-leaved Cherry (*C. R.*).—There is nothing for which this Cherry is remarkable, except its large leaves and high sounding name; however it came to be called "Four-to-the-Pound" would puzzle anyone to imagine, but such is the name by which it was at one time known, and under which it was found in all nurserymen's catalogues. It is a very old Cherry, and is evidently of English origin, being mentioned by Parkinson as early as 1629, under the modest designation of "Ounce Cherrie." He says, "The Ounce Cherrie hath the greatest and broadest leafe of any other Cherrie, but beareth the smallest store of Cherries everie yeare that any doth, and yet blossometh well; the fruit also is nothing answerable to the name, being not great, of a pale yellowish red, neere the colour of amber, and therefore some have called it the Amber Cherrie." There is no doubt it is this variety also which is described by Meager under the name of Ciliegeberrylin," which he says is "as big as an indifferent Apple." The Germans ascribe its introduction on the Continent to the Earl of Murray, who had a seat at Menin, in Flanders, whence it was taken into Germany by M. Seebach, colonel of an Austrian regiment of cavalry, and who received it from Lord Murray's gardener under the name of Quatre à la Livre. The leaves are a foot and sometimes 18 inches long."

Preserving the Colours of Leaves (*G. R.*).—The plan here described is recommended by a lady who has been successful in preserving autumn leaves:—As soon as possible after gathering them the leaves must be pressed. If they begin to wilt or shrivel before you are ready to press them, put them in water and keep them there until they revive. See that no soil, no foreign substance of any kind, is on either side, and then with a warm, not hot, flat iron press and iron each leaf on its upper surface till it is perfectly dry, spreading it for this purpose on several layers of paper, or on an ordinary ironing-board, just as if it were cotton cloth. This over, oil each leaf on the same side on which it was ironed with linseed, olive, or lard oil, using a small camel-hair brush or a bit of cotton batting tied to a stick, and then place them on dishes in the sunshine to dry. When dry reject all those that have a semi-transparent or oily appearance; to prevent this get the thickest leaves you can for your collection, and do not oil them too generously nor with a rough brush. It is a mistaken notion that autumn leaves need varnishing. Varnish makes them brittle and more liable to crack, while the excessive lustre that it imparts is unnatural. Oiling gives sufficient polish, deepens, clears, and preserves the colours, and keeps the tissues somewhat elastic. When the leaves get dusty wipe them with a damp cloth; if they curl damp them, and place the branch for a few hours between papers under a pile of heavy books.

Propagating Indiarubber Plants (*A. G.*).—The following methods, successfully practised by an old grower, will answer with you if carefully carried out:—The present time is suitable for propagating this plant, either by shoots taken off with a heel or by eyes. When it is propagated by eyes they should be taken with a leaf attached to each, and be placed in silver sand to keep them from bleeding. Insert them in small pots well drained, in a mixture of peat and cocoa-nut fibre, and plunge in a strong bottom heat of 90°, with a little sand under each cutting. If they are not placed in a strong bottom heat the eyes will not break. When the eyes have rooted and commenced growing they should be repotted into 48-sized pots, in equal parts of turfy loam and peat, with sufficient sand to keep the soil open. The plants should be placed in a temperature of about 70°, and be syringed frequently; occasionally sponging the foliage is also highly beneficial. The plants should never be allowed to become potbound until they have grown to the allotted size, when they will be greatly benefited by liberal supplies of liquid manure. During their growing season they should never be allowed to become dry at the roots, as dryness causes the leaves to turn yellow and spoils the beauty of the plants. Shoots taken off with a heel will make plants much quicker than raising them from eyes; and it is the safest plan, for if strong bottom heat is not afforded, the eyes, as before mentioned, will not break into growth. When only a few plants of rapid growth are required we advise that they be raised from cuttings, but when a great number of small plants are required, which is not unfrequently the case now Indiarubber Plants are fashionable, the mode of raising them from eyes must be resorted to. Plants are now in great demand, and are being rapidly increased by the above modes in most nurseries, and they have a large sale in Covent Garden Market.

Culture of the Cranberry (*W. W.*).—This agreeable fruit may be easily cultivated. It grows naturally in low boggy places, or on wet moors amongst the bog moss. This moss, rising gradually up above the level of the water, forms, as the lower parts decay, a bed in which the Cranberry flourishes and bears fruit abundantly. To cultivate it near home we must imitate the situation in which it grows wild. To accomplish this fix upon a situation near to a supply of water, then dig out the common soil 4 inches, and fill up the place with bog earth; raise up this peat 6 inches above the level; then form a trench round the bed a foot or 16 inches wide, puddling it at the side next the common soil and at the bottom with clay. Keep this trench full of water. Plant the Cranberry plants in the raised bed a foot apart every way; they will soon run over the whole surface and bear plenty of fruit. The water should be frequently changed or it will become foul. Should there be a small lake, or even a large one, near at hand, an excellent Cranberry bed might be made near to the side. All that would be required would be to form a low flat island with a peat earth surface, the Cranberry plant put in it at the proper distance, and kept clear from weeds. This might be named with propriety, "The Cranberry Island." A small extent would produce a large supply of fruit. If

the island was 8 yards long and 4 wide it would be quite large enough to supply a moderate family. Lastly, this fruit may be grown in a bed of peat 1 foot deep, sunk an inch or two below the general surface, and during dry weather be flooded with water occasionally. In this bed they will fruit to a middling extent. This last method is, however, not nearly so good as either of the former; it should only be adopted where the situation will not admit of either of the other being practised. The American Cranberry, on account of its size, is the best to be cultivated.

COVENT GARDEN MARKET.—JANUARY 1ST.

OUR Market has been well supplied with all classes of goods for Christmas; Grapes especially were good and reasonable, Pears alone being short and high priced. Business generally has not been up to the average.

FRUIT.

A HAPPY NEW YEAR.

QUICKLY run the sands of time; another year ended, another year begun! How can we best turn to account the lessons of the past so as to insure a bright and prosperous future? For we are very sure that farmers and prosperity have not parted company for good and all. On the contrary, it is gradually coming back to us, and the more fully this is realised and the more clearly the manner

of its return is grasped by our readers the more able will they be to obtain their full share of it, and to enjoy the Happy New Year which we so cordially wish them.

No radical change is there in the agricultural situation, nor is there likely to be any such change brought about by State aid in the guise of protection. It is to themselves alone that farmers must now look for relief; nor is it difficult to see how they may do so. Rent has come down with the price of corn, and good sound land can be hired at "time's prices," which means really a fair and reasonable adjustment of rent to the present value of farm produce. Taken upon this sound basis land ought to answer under really good cultivation quite as well as it ever did; and it does. No doubt there is a serious curtailment of means among farmers generally; but this by no means points to unprofitable farming, but rather to small profits, which it is now our aim to realise as quickly as possible.

As mixed and modified husbandry takes the place of exclusive corn-growing prosperity returns, especially to those who are striving earnestly for improvement in every detail as well as the actual system of their practice. That faults abound in ordinary farm practice there can be no doubt. Ignorance, prejudice, carelessness all tend to cripple the farmer, and it is exceptional to meet with intelligent striving for improvement. Read, mark, learn, as well as practise, say we to every farmer, and do not let prejudice and custom stand in the way of improvement. Only an hour or two before sitting down to write this article we asked a Kent dairy farmer what place green Maize had among his crops, and were told that Maize would not answer in Kent. A little inquiry showed us that he was quite ignorant of the high value of this crop, as well as of the simple process involved in its cultivation. We ventured to say he was altogether mistaken, and gave him the necessary details with a hope that he might be induced to try this finest of all green forage crops for early autumn use.

Before all things a tenant farmer should resolve to turn every yard of land for which he pays rent to full account, and he should next set himself earnestly to see how he can best do this at a moderate expenditure. Good farming does not consist in the production of heavy crops and numerous fat stock at an outlay which absorbs all profits, but rather in a system of management which insures a certain profitable return upon outlay every year. In order to do this the outlay for labour must be confined within given limits, the crops must be well balanced, the live stock must be well bred, brought to early and profitable maturity, and not be kept simply for the manufacture of manure. Waste is a crying evil on many a farm, and we repeat that there is much waste in the formation of huge muck heaps, from the feeding of the cattle, the reckless use of hay, roots, and straw, onwards to the carting, turning, recarting, and final spreading of what is termed manure, but which too frequently is mere sodden humus.

Very much is done to enable farmers to avoid wasting money upon adulterated cattle food and manure by the Royal Agricultural Society of England and similar associations, yet for the majority of farmers the analyses published do no good. They are content to continue purchasing cake and manures about which they know nothing, simply because the cake has some nourishing properties, the manure some elements of fertility, without having regard to much worthless matter contained in both, upon which they are content to waste money. Repeatedly have we had evidence of this in Dr. Voelcker's reports, yet the sale of such rubbish continues, to the disgrace and loss of the easy going purchasers. Individual effort can do very little to grapple with this matter other than by a strict avoidance of dealers in such articles. But local Agricultural Chambers and Farmers' Clubs would be doing good to form companies whence farmers could obtain their supplies with a feeling of certainty that they are having pure genuine food and manures at the lowest market price. Failing such advantages, expenditure upon cake and manures may be avoided by using home-grown food and an extension of sheep folding, which, after all, is

the most economical and certain method of imparting fertility to the soil. That this would be done more generally we have no doubt if each farmer would keep well within the compass of his means and only hire as much land as he could afford to manage in the best possible manner.

WORK ON THE HOME FARM.

The last week or two have been very busy ones at the homestead, an extra supply of all kinds of our home farm produce having been required for Christmas festivities. Care was taken to send an ample store of Oats, hay, and straw up to the Hall stables in good time for the extra horses, of which there are always several coming and going at this season of the year. Carriage horses are easy to calculate for in comparison to hunters, as they consume a given quantity of corn with very little variation; but for hunters there must be an unlimited supply, only taking care to have it slightly crushed before delivery to the stables. It should never be forgotten that much corn is wasted by being used uncrushed, as it is very liable to pass through the stomach of an aged or overworked horse without being digested. There is a decided preference for old winter Oats both in hunting and training stables, and the home farmer should make it part of his especial business to always have a full supply of this corn, well screened, and weighing at least 42 lbs. to the bushel. A few old Beans are also much liked.

Good meadow hay will always pass muster with stable managers, but individual fancies are wont to crop up for savoury Clover and Sainfoin hay, or sweet old Rye Grass hay. We have always found it good policy to make all reasonable concession to meet such fancies, as they are practically harmless, and the difference in value is immaterial. It is a good and economical plan to arrange to supply such stables regularly with chaffed forage, so that by mixing winter Oat straw chaff with that of hay and stover much saving of hay may be effected. Nothing but the best Wheat straw is considered suitable for light horses, but we continue to mix a large proportion of the best Barley straw with it, and when the threshing has been well done we have no complaints.

Perhaps really good butter is more highly appreciated at this season of the year than any other. Enough cows have calved recently to enable us to reserve cream from their milk for the daily churnings for the table butter pats, and so avoid all risk of the unpleasant flavour which is apt to be found when cream from stale cows is used. The most scrupulous care is taken with cowhouses, yards, and food now, so as to avoid all risk of imparting any taint to the milk. There is also a sink in the milking shed with water laid on, a hand bowl, soap, and a coarse roller towel to ensure clean hands for the milking.

REVIEW OF BOOK.

Farm Live Stock of Great Britain. By ROBERT WALLACE, F.L.S., F.R.S.E., &c. Second edition. Edinburgh: Oliver & Boyd, Tweeddale Court. London: Simpkin, Marshall, & Co. 1889.

NOT an easy matter is it to find a niche in agricultural literature for any new departure, however novel may be its features, but in "Farm Live Stock" Professor Wallace has certainly done so. Very modestly does he tell how he has striven to render his work of especial value as a text-book for students of agriculture, and of interest to the general reader. He has done much more than this, for a careful perusal of the work has brought conviction that it may be taken as a guide and counsellor by farmers generally. Take, for example, the "General Management" of pigs. Here we have the form of the sow, the time and full particulars of breeding, and are told how a sow may be induced "to have five litters in two years by beginning to feed the young on milk at two or three weeks old," which goes to show that early maturity in breeding as well as in fattening is possible under good management. Under such treatment a sow is ready for breeding at the age of six months. The first litter is put at the reasonable number of six or eight pigs, and subsequent litters at ten or twelve.

"Pigs," we are told, "are the most economical meat producers on the farm. They consume more food per 100 lbs. live weight than either sheep or oxen, and have much greater capacity for assimilation in the intestines, though their stomachs are small. They consequently require concentrated or digestible food." Much other useful information is given, and amongst it we may call particular attention to a table setting forth the cost of producing a stone (14 lbs.) of pork, which shows that a net profit of 1s. per stone may be had in addition to the manure. This calculation is based upon the assumption that pig meal costs, inclusive of grinding and carriage, £5 7s. 10d. per ton, but reference to the lowest quotations shows that it can be had for considerably less than this.

Equally forcible and useful examples might be quoted of cattle, sheep, and horses, but we give preference to pigs, because we cannot too frequently impress upon farmers the fact of upwards of eleven million pounds (£11,000,000) being paid annually to foreign producers for the pork, lard, bacon, and hams imported into this country, all which could so clearly be produced by British farmers profitably. Assuredly we have no just right to clamour to the State for protection, or help of any sort, when we will not help ourselves.

Among other special features of this useful work are its photographic illustrations of typical animals of the various breeds, with historic sketches, based upon the standard works of Youatt, Coleman,

Low, Shields, Pringle, Wrightson, and Sheldon. This novel method of illustration is commendable as conveying a good general idea of the characteristics of each breed, but as yet it fails to emphasise prominent individual features as the pencil of an artist would do. The principles of breeding are clearly set forth, and are of much value, as also are the points of breeds and cross-breeds, and the author's estimate of their comparative value for the production of milk and beef.

We entirely agree with Professor Wallace upon the evils of the rough-and-ready treatment of foot-rot by driving an entire flock periodically through a trough containing a certain specific. The plan itself is a bid for carelessness. Foot-rot is contagious, and the only safe method of treatment is to take each case, and treat it strictly according to its special requirements. The author's advice about other diseases of farm animals is equally sensible, and his description of the symptoms of different ailments may be taken as a guide which will not mislead. Of swine fever we are told the symptoms are "costiveness in the first and diarrhoea in the second stages, with dullness, shivering, great thirst, and listlessness; the skin covered with red and black patches." Surely nothing can be more graphic or pointed, for we have every prominent symptom before us at a glance.

In the last chapter we have examples of stocking farms in the southern and midland counties in full detail, the difference in the requirements of light and heavy lands being shown, and a balance sheet is appended showing an amount of profit which farmers generally would be glad to realise in these hard times. Without dwelling upon the calculations given to show how such profit is realised, we may usefully commend them and the teaching of the entire book as eminently calculated to promote that which the author has evidently at heart—i.e., the prosperity of British agriculture.

OUR LETTER BOX.

Egg-bound Hen (*Jas. Helsby*).—There are various causes, amongst others overfeeding, a soft-shelled or very large egg blocking the egg passage, &c. Oil the passage with a feather, or inject into it some sweet oil. Hold the affected part over a pailful of boiling water, which will greatly assist the expulsion of the egg. Handle the bird very gently, as rough usage is apt to break the egg inside of the bird, which generally proves fatal.

REMARKS.

- 22nd.—Wet till 7 A.M.; fine morning, with some sun; wet afternoon and evening.
23rd.—Sunshine all the morning, dull afternoon and evening.
24th.—Showery morning; fair afternoon with some sunshine; clear night.
25th.—Fine and bright throughout.
26th.—Fine, but without sunshine.
27th.—Cloudy throughout.
28th.—Cloudy and cold.
Considerable variation of temperature, but the mean very near the average.—G. J. SYMONS.

COMMENTS ON FRUIT CULTURE.

"*D. DEAL*," in his comprehensive and genial New Year's greeting refers to the progress that has been made in flower, vegetable, and fruit culture during the past year. In respect to the latter he says, "A great movement has taken place, and, as is usual with us, we have been rather inclined to ride the hobby to death. While there is no doubt much to be done by the better cultivation of better sorts, as has been well shown in the Fruiterers' Company's prize essay on fruit growing, yet that fruit is ever in this country to take the place of any of our other products or drive the foreigner out of our markets is a wild chimera." Those sentences are worthy of repetition and brief comment.

In preparing the essay referred to I endeavoured to avoid indulgence in the extravagant utterances that have been far too common and certainly misleading in newspapers and magazines on the subject of fruit. Such statements as of £6,000,000 to £8,000,000 being expended on fruits that "might be grown at home" have been so often repeated as to have sunk deep into the public mind as the truth. They are not true. The value of the importations of Currants, Raisins, Oranges, Lemons, Bananas, and various other tropical fruits are included in the importations, and in fact form the chief bulk of them, and only a visionary would suggest that the supply of them necessary for meeting the consumption in this country can be grown here; and I am in entire accord with "*D. Deal*," that the idea of driving the foreigner out of our markets as a producer of fruit is a "wild chimera." I go further, and say if such a thing should by any possibility happen it would be a misfortune to us as a community. Instead of abusing the "foreigner" for sending us such good, full, and generally cheap supplies of fruit of the nature indicated we should thank him for his enterprise, and if home growers of hardy fruit have failed to produce more, and of the first marketable quality, whose fault is it? Not the "foreigner's" surely. No, the fault is at home, and the most hopeful sign of the times is that it is at last admitted—hence the "great movement" referred to, and which will as surely result in more and better fruit being grown in this country as the sun will rise to-morrow.

The fact that millions of bushels of Apples are brought from over the sea, and sold in our markets yearly, demonstrates the inadequacy of our home supplies, but not in bulk so much as in appearance. I am not quite sure the expression of my belief now to be recorded will not expose me to an avalanche of hostile criticism. That must be risked. My belief is that, weight for weight, the practically worthless and unsaleable home-grown Apples in good Apple years exceed the importations of handsome-looking well sorted fruits that come from distant shores, and are sold in shops nearly all over the kingdom. I am convinced from not very limited observation that such is the fact, and I am equally convinced it ought not to be, and will not be in a few years' time. If owners of exhausted orchards in different parts of the country are content to rely on their produce so much the worse for them, and so much the better for those more enlightened cultivators who are planting the best varieties in the best manner in the best soil at command, for the fruit from these trees, properly marketed, will sell at the least as well as any that can be brought from other lands, and probably better, for the best culinary Apples of Great Britain

possess a piquancy and briskness all their own that is bound to be preferred to the comparatively insipid and "flat" tasted imported samples. The millions of purchasers in cities do not know this, because they see so little home-grown fruits good enough in appearance to tempt them to buy and find it out. They buy that which looks the best when prices are reasonable, and when they are not they go without. The first essential of fruit for sale is good appearance, as represented by size, uniformity in sample, and colour—not necessarily redness but clearness, though the British matron undoubtedly likes a "bit o' colour." Yet well grown, firm, fleshy, juicy home-grown yellow Apples, free from specks and bruises, sell well at good prices to the grower when he has good crops to sell.

This brings to the front another point that cannot be overlooked by practical men, and it is this—no matter how good the varieties, how suitable the soil, how skilled the cultural attention, good crops of Apples cannot be relied on with anything like certainty every year. The most correct methods of pruning may be practised, the best of manures employed, insects may be subdued, and perhaps caterpillars conquered; but man with all his wisdom, though he may guide his trees into blossom and rejoice in their beauty, may be compelled to see it fall and leave little or no fruit behind. The organ of fructification may be imperfect, as was the case with so many last spring through the influence of the cold and wet preceding summer; bright sunny days and keen frosty nights may occur during blossoming time, or a week or ten days of rain. All these are natural incidents that have happened in the past too frequently, leaving the trees barren, and they will occur in the future. From these visitations alone many persons who are planting trees so hopefully, and counting on their yielding estimated amounts yearly, will sooner or later be greatly disappointed. There will be seasons in which they will have no fruit, just as during the past year thousands of trees in the best condition for bearing, and watched and cared for by the most expert cultivators, had not a fruit on them. That there are sanguine persons expecting more than they will realise from planting fruit trees is certain—some through the natural obstacles alluded to, others through errors in choice of varieties, and bad planting in unsuitable soil and unfavourable situations. Acres of trees have been "stuck in" during the last two years in a manner and in soil in which they cannot thrive and prove remunerative. In this respect the "hobby is being ridden to death." Sound information was never so much needed on the subject of fruit culture by so many persons as at the present time, and I cannot advise persons who have little or no experience to guide them, and little or no money to lose, to invest in one kind of fruit alone, such as Apples or Plums, as so many are disposed to do. They may find it weary waiting for the crops, and hard to live in the meantime, therefore I strongly urge the desirability of not overlooking what are known as small soft fruits for affording quick returns for immediate use and preserving. Any one kind of fruit—such as Apples, Plums, and Pears—is liable to fail; but I have never known a year when all fruits have failed, and the small are more certain in bearing than the larger kinds.

Another thing, and this brings me, perhaps, slightly in conflict with the dictum that "fruit will never in this country take the place of any of our other products." I think jam has taken the place of butter in the meal of many a hungry child. Thousands of such meals have from time to time been provided by the kindly disposed to children in Board schools in the poorer districts in London, and jam largely, palatably, and wholesomely, takes the place of grease in humble homes innumerable, and possibly in some that are not destitute of the comforts or even of the luxuries of life. But much jam is, comparatively speaking, horrid stuff, though more, I am glad to believe, is excellent. For pure, wholesome, first class jam, in which the fruit is not smashed to obscure its identity, we ought, with our facilities for its production, and the

cheapest sugar in the world, have the world for a market, and establish an export trade far greater in extent and far more valuable than the imports of raw hardy fruit into this country.

The Fruiterers' Company are endeavouring to afford guidance to those who need it on fruit culture. There can be no doubt of their earnestness and disinterestedness in the matter. It is not a company of wealth, but of influence, and the confidence it enjoys is apparent in the contributions towards raising a sum of £5000 for investment, the income therefrom to be devoted to the encouragement of the object in view. Large professional fruit farmers need no encouragement. They can look after themselves, and prizes of a few pounds would neither do them nor anyone else any good. With cottagers and small farmers it is different, and it is that great class—the least well-to-do of all workers on the land—who require such assistance as can be given for bettering their condition. In what way this can be best accomplished will no doubt be the subject of grave deliberation. On this subject the *Midland Counties Herald* makes a suggestion that is bound to have the consideration it merits. Our contemporary says:—"Let the Fruiterers' Company search out a few competent men and set them to teach our country folks how to cultivate fruit trees profitably by a series of lectures and practical illustrations of the art of pruning, which can rarely or never be acquired from books alone. They can commence operations on a small scale, and might start in one or two parishes in favoured districts during the winter months, and in the spring and summer following outdoor illustrations might be given of the various operations involved. Under no circumstances would such efforts made to instruct the people be quite without effect, and the chances are they would prove most beneficial."

There cannot be a doubt that practical teaching of the nature indicated, or lessons given in the garden, so to say, by persons who are competent to show by example how to plant and prune, and to explain the reasons of the different operations, would be the most effectual. The Fruiterers' Company can no doubt find the men if the means are forthcoming to do what is suggested. It is a question of means, and it is conceivable there are landowners sufficiently wealthy who would be glad to engage, through the Company, men who could give such lessons as would enable their tenants to grow much more and better fruit in the future than has been grown in the past for the benefit of their families and the inhabitants of the surrounding districts, while the value of the land would be enhanced. Also I know there are persons who have a few hundreds, and even a few thousands of pounds at command who are most desirous of investing in fruit culture, but entirely without experience, who would most decidedly find it to their advantage to engage a competent man at the outset who could advise on the suitability of the land inspected, its preparation for planting, the selection of varieties of fruit, and all other matters on which success depends. Fruit will be so plentiful in the course of a few years, when the seasons are favourable, that only those who have commenced its culture on a good foundation will realise with some approach to their expectations. There are plenty of teachers by the tongue and the pen who can neither plant nor prune, but they are not the men to inspire confidence as guides in the important work in question. Perhaps the time may come when the Fruiterers' Company will be in a position to recommend advisers who have proved their competency in fruit culture by long experience and successful work. These alone are to be relied on, and it is only those that a responsible body could afford to invest with authority to represent them.—J. WRIGHT.

PLANTS CERTIFICATED IN 1889.

THE commercial value of certificates awarded to new plants was illustrated in a legal action that attracted much attention during the past year, and it was also convincingly shown that those awards only carry special pecuniary value when the person to

whom they are adjudged possesses the entire stock of such a novelty. At the same time, any plant that has been certificated acquires a certain general importance that nurserymen are not slow to take advantage of by announcing the fact in their catalogues, even though they were not the recipients of the honour in question. Where a stock is in hand of the identical plant this course is perfectly justifiable, and is equally open to all. The special object of a certificate is to stamp an exhibit, whether plant, fruit, or vegetable, as meritorious, and distinct from others of its class. The benefit derived by the trade is incidental, but no doubt considerable. If the onerous duty of awarding certificates be performed justly and with the exercise of keen discrimination, the value of such awards to purchasers should, however, be much greater, and it speaks volumes for the honesty of British nurserymen that they voluntarily submit so many of their acquisitions to the critical examination of independent experts. It is sometimes urged as indicating certificates do not possess the value supposed, that many useful garden productions have found their way into general cultivation and favour without such recommendation. This is true, but the process of gaining popularity is a longer one, and possibly more expensive too. At any rate, this is being recognised by the majority of those concerned with the introduction or raising new plants, and the numbers submitted to the Floral Committee increase rather than diminish, as some have predicted.

Since 1859 the Floral Committee of the Royal Horticultural Society has performed invaluable service in according official recognition to deserving novelties, and a complete descriptive record of the plants exhibited and certificated during these thirty years would constitute a most important work of reference. For some years certificates in two grades, first and second class, were adopted, but as some dissatisfaction was expressed with this arrangement, and the second class certificates not only failed to possess any value, but even came to be considered a stamp of inferiority, they were discontinued. The awards were then restricted to first class only, with botanical certificates for plants possessing some interest structurally or otherwise, but not sufficiently attractive to rank as garden plants for decorative use. Last year a new system was inaugurated, which caused a little confusion at first, but ultimately was found to work well, and it will no doubt be continued. The "first class certificate" was continued for plants of special distinction and merit; and for those that still deserved notice, while not perhaps of such pronounced characters as the others, an "award of merit" was instituted, thus permitting the Committee to recognise many plants that would otherwise have been passed or placed on an equality with those of a superior character. It was also stated in the new rules that "in quite exceptional cases gold, silver, or bronze medals may be awarded for objects of extraordinary merit," but in the only case where advantage was taken of the latter privilege, and a silver medal awarded in addition to the first class certificate for a new Orchid, a difference of opinion arose between the Committee and the Council, and whether the medal was ultimately awarded or withheld has not transpired.

Another useful condition was also introduced to the following effect:—"The Committees will recommend awards to be made to very superior seedlings or novelties, or to recently introduced, re-introduced, or very rare objects, or to highly decorative plants, according to their merits. In the case of plants commonly grown from seed every year, the award will be made to the 'strain' and not to individual plants." Something of this kind had become necessary, for in the case of *Calceolarias*, *Cinerarias*, and even of Chinese *Primulas* and *Tuberous Begonias*, the varieties have been so rapidly multiplied, such a great advance has been made with these and other plants, that from a good strain of seed scores of varieties are obtained every year quite as good as those formerly certificated. Of course even now exceptionally distinct novelties are occasionally secured, and special awards are then justifiable.

The cultural certificate, an important award that ought to be granted freely in all cases where really good culture is displayed in the production shown, was continued. Botanical certificates were entrusted to the Scientific Committee, and beyond these were the Chiswick certificates. Here some explanation is needed, as there has been a misunderstanding with regard to the awards made at Chiswick. Plants, fruits, and vegetables sent to Chiswick for trial are inspected by the Committees at special meetings during the year, and certificates are awarded to those considered worthy of recognition, but these are more of comparative than absolute value, and are distinct from the certificates granted at the ordinary meetings of the Committees. With regard to most vegetables it is, however, indispensable that they be tested in the Chiswick gardens before they can gain an award from the Fruit Committee.

From the time the Fruit and Floral Committees were established

until within the past few years these two bodies were entrusted with the whole of the awards for novelties, but a short time since when the Daffodils became so numerous and popular, a special Committee, or rather a sub-Committee, was appointed to deal with them, and as it included several members of the Floral Committee, with some specialists added, the meetings were appointed to be held after the Floral Committee had performed their duties. This was found to answer well, and led to a suggestion that more sub-committees should be formed for special plants; the only result, however, was the somewhat hurried institution of an Orchid Committee after the arrangements for the year were announced. Doubts have been expressed as to whether this was needed, but in many respects it was very desirable that a special body should deal with these plants, and it was thought that members possessing an intimate knowledge of Orchids being in a minority on the Floral Committee, they were likely to be outvoted upon some occasions, though they were unanimous among themselves. At least there was as much justification for having a separate committee for Orchids as for Daffodils, but it was unfortunate that the same plan was not adopted with both—namely, having the meetings after the Floral Committee instead of at the same hour. It has been contended that the Floral Committee was weakened by this course, and when, as happened at several meetings, there was not sufficient to engage the Orchid Committee for more than fifteen minutes, it is obvious that members who give their services, and in some cases travel a long distance, might excusably wish their time had been better employed. Such difficulties would be readily overcome by altering the times of the meetings of the two Committees, it has been frequently suggested. Many are in favour of it, and I can see no reason why such a plan should not be adopted. Now the Fruit and Floral meetings are to be held at twelve o'clock instead of eleven as previously, it would be quite easy to let the Orchid meeting follow the Floral, the Society would utilise the services of more members, and be able to maintain the full strength of the Floral Committee.

Last year a new method was also tried in the registration of certificates, and with some slight improvements suggested by a year's experience, it will no doubt be an improvement upon the old system. The innovation consisted in recording the number of votes for and against each plant certificated, or proposed to be so honoured, so that the public can form some idea as to the relative merits of the plants brought before the Committees. Unfortunately a difficulty occurs in this respect, that while one plant may lose a certificate by a single vote, another of no greater merit might gain the award by one vote, depending perhaps upon the number of members present. It has been suggested that some definite proportion of those present should be required to vote in favour of a certificate before it be granted, but this would be difficult to carry out in practice, though it certainly does not seem fair that one vote should either give or prevent an award. It would not be unreasonable to require a majority of at least three votes to carry a certificate.

The Royal Horticultural Society's Committees and methods have been dealt with thus fully because they are rightly regarded as the leading authorities in these matters; but there is another Floral Committee—that of the National Chrysanthemum Society, which, in its own special department, performs an important service as any of the others. Nearly all the leading Chrysanthemum novelties of each year are now submitted to its inspection, and its decisions are invited upon critical matters of judgment. It is probably due to an oversight that "D., Deal," in his excellent leader last week reviewing the past year, omits all mention of this Society, though the National Rose Society is accorded the notice it so well deserves. Any unprejudiced observer must admit that the National Chrysanthemum Society has done good work, and it has in this been aided in no mean degree by the labours of its Floral Committee.

It is somewhat strange that the larger provincial horticultural societies have not adopted the plan of forming small select committees for certificating novelties. Such awards would possess more weight than those granted by judges, for in an ordinary way certificates are bestowed very liberally at country shows, and for such diverse objects that they do not bear any special value. Thus in some instances certificates are awarded for miscellaneous groups and exhibits of all kinds, as well as for novelties, and there is a prevailing idea that as such awards cost the societies nothing they can be given in lieu of prizes. There are always many good novelties that do not reach the London Committees until perhaps enterprising tradesmen have purchased and exhibited them, so that the institution of local certificating committees would not interfere in any way with the central committees. At the Royal Botanic Society's shows, and those held at the Crystal Palace and elsewhere, similar methods might be also tried.

Having devoted so much to generalities, a review of the plants that obtained honours during 1889 must be reserved for another issue.—LEWIS CASTLE.

ORCHIDS ON CEMENT BLOCKS.

MR. A. H. SMEE is always either making experiments, or encouraging his gardener to make them, in his interesting garden at Wallington. In one of his houses a *Laelia*, if I remember rightly, has been hanging from the roof near the back wall for some time. The wall is cemented. The roots of the plant reached it, clung to it, and have extended in a remarkable manner. Several other Orchids were then attached to pieces of cement flooring an inch or so thick, and, without an exception, the roots have "taken to" it with the utmost readiness, and sickly plants so attached have soon improved considerably. *Phalenopsis* and other kinds are pointed out with healthy roots clinging to the surface. Mr. Cummins mixed some cement and sand, thus making a new block, and it appears to be answering as well as the old. Lumps of cement are also being used in pots for Orchids instead of crocks and charcoal. A new house has been erected by Mr. E. Newton for Mr. Smee's fine collection of *Cattleyas*. It is dry glazed on the "reform" system, very light yet strong and drip proof, also amply ventilated. It is expected to answer well. A Peach house is similarly glazed, and by a simple contrivance boards can be fixed on the roofs of these houses for the insertion of a square of glass as may be needed, paint or putty not being required by the light yet strong galvanised bars.—VISITOR.

CATTLEYA O'BRIENIANA.

At a recent meeting in the Westminster Drill Hall, Messrs. Sanders & Co., St. Albans, exhibited a group of Orchids, including

FIG. 4.—CATTLEYA O'BRIENIANA.

one under the above name, of which a flower is depicted in the woodcut (fig. 4). It resembles some of the small-flowered *Cattleyas*, and is probably a variety of one of these. In any case, however, it is attractive, the flowers of a soft rosy tint, a little deeper at the margin of the lip.

YELLOW TOMATOES.

I WAS much interested in Mr. Iggulden's article, page 525, on the above, but I must take issue with him as to the quality of Golden Sunrise. I am quite at one with him as to its beauty, &c.,

but I firmly believe it to be nearly, if not quite, the best flavoured Tomato grown. I am quite aware that it takes some years to educate your taste sufficiently to discriminate between the delicate differences of flavour in Tomatoes, and I can only suggest that Mr. Iggulden's taste is now in a transition stage. When fully educated, his taste will esteem Golden Sunrise at its proper value. I gave a plant to a gentleman who planted it against a wall, and to the same gentleman I sold several small quantities of fruit grown under glass. Now this gentleman is a Tomato connoisseur, and gives a good many dinner parties, and he came to me one day and said, "That yellow Tomato of yours is the best flavoured I ever ate, and all my friends say so also." Another gentleman, also a connoisseur, was continually asking me for some, and said he never tasted such a Tomato. Many others said the same, and only having planted four or five of this variety I found it hard to satisfy inquirers after Sunrise, for no sooner was a fruit ripe than it was wanted by several people. "The proof of the pudding is in the eating," as no doubt Mr. Iggulden has found out this Christmastide, and the proof of the high quality of Golden Sunrise is in the great demand for it by all who had tasted it. I prefer the evidence of so many gentlemen with highly cultivated taste to that of my friend, Mr. Iggulden, with whom I will agree to differ.—H. S. EASTY.

NOTES ON FORCING VEGETABLES.

POTATOES.

THIS extremely valuable root, although capable of being preserved from one season to another, is nevertheless required in a young state nearly three-fourths of the year, and various modes have been tried to produce this esteemed vegetable at an early period of the year. It does not require a high temperature, but like many other exotic vegetables it is extremely impatient of frost.

The most general and successful mode of forcing is upon beds of hot dung or leaves, or both mixed together. For the purpose a quantity should be prepared by repeated turning and fermenting, until all the rankness evaporates, and when in a proper state to make a hotbed it should be placed together to the height of about 3 feet. In the process of making the bed the dung and leaves should be well shaken out and pressed down with the back of the fork, but not trodden. When finished the frame and lights should be placed on. In a few days, if the dung has been properly prepared, the bed will be ready to receive the plants. A quantity of light soil mixed with some good leaf mould and manure from old Mushroom beds should be spread over the bed to the depth of about 6 to 8 inches. In this the Potatoes, which should have been previously started by being placed in boxes among leaf soil and well rooted, should be planted in rows about 15 inches apart, and 8 inches from plant to plant. They must not be allowed to suffer from insufficient water, and air should be admitted on all favourable occasions, or they will be drawn up weakly, and the crop will not be so good. The temperature should be from 50° to 60°, allowing it to fall a little during the night. Should frost or cold winds prevail the frames should be covered at night with mats, &c.

Where Potatoes are wanted very early they may be grown in pots, 15 size being most convenient. The pots should be well crocked and half filled with soil, three tubers being placed into each pot and covered with soil, arranging the pots in a temperature of about 60°, with a little bottom heat if it can be had. When they have grown about 4 inches or so, the pots should be filled with soil mixed with a little of Thomson's or Clay's manure, just leaving about half an inch for watering.

They can also be successfully grown in heated pits or frames without any bottom heat. The tubers must first be started in boxes, and be well rooted before being placed in the pits or frames. Medium sized tubers uncut with all the eyes rubbed out with the exception of the three strongest are the best. Planting is best done with a spade, and a little old Mushroom-bed manure can be placed in the bottom of the drill before the Potatoes are placed in, and they should also be covered with the same or leaf mould. A little of some artificial manure sprinkled along the line is never lost. The lights can be kept closed till the Potatoes are up, after that air must be given on all favourable occasions. A temperature from 50° to 60° suits them. When water is required it should not be given from the cold water tank, but be warmed a little before being applied. When the shoots are a few inches high the soil should be drawn to them with a hoe.

The sorts I have found do best are Mona's Pride, an excellent cropper and capital in flavour. There is no complaint when this goes to the table. Early Dwarf-top Ashleaf, the true old sort, is also first rate for frame work, and excellent in flavour. Sharpe's

Victor is also very good and forces well, but I like the two above mentioned quite as well.

CARROTS.

These are very easily brought to perfection by sowing the seed on hotbeds of dung or dung and leaves any time from November till they can be pulled from the early border in the kitchen garden. As a mild temperature only is required the bed need not be more than 2½ feet high after it has settled, and is ready for the seed being sown. After the frame is placed on the bed, a little more dung and leaves should be added, to bring the bed to within a foot of the glass. On this should be placed 4 or 6 inches of light sandy soil, and when it is considered in a fit state to sow the seed—that is, when all rank steam has gone off and a mild temperature is maintained—the seed may be sown broadcast and just covered, or it may be sown in drills 6 inches apart and half an inch deep. A few Radish seeds may be sprinkled over the bed and raked in, which will be found to prove acceptable. A temperature of about 50° to 60° will do very well, or even less towards spring.

When the seeds have germinated admit plenty of air, but avoid cold draughts. If they are too thick they should be thinned a little, but not overmuch, as they will be used when small. If the bed becomes dry water the same temperature as the bed must be given. Weeds must be kept down. If the beds become cold fresh hot manure should be placed round the frame, first pulling away some of the outside of the bed to allow a greater quantity of hot dung to be added. The best sort for forcing is the early French Short Horn.—G. HILTON.

EVENTS OF THE WEEK.—The Royal Horticultural Society's Fruit and Floral Committees will meet in the Drill Hall, James Street, Westminster, on Tuesday, January 14th, at 12 noon. In the afternoon the Rev. W. Wilks will read a paper on "Winter Gardening." The annual dinner of members and friends of the Gardeners' Royal Benevolent Institution will take place at Simpson's, on Thursday, January 16th.

— THE WEATHER.—In the south of England the weather of the past few days has been quite mild and spring-like, and upon one or two nights the temperature did not fall below 45°. Much rain has fallen, but the earlier part of Tuesday was extremely clear and bright, and the temperature was remarkably high, averaging in the metropolis about 52°, or more than 12° above the mean for the month. Indeed, it was more than 2° warmer than the average temperature for the whole year, and would have been just about right for the 1st of May or for the middle of October.

— THE SEASON ON THE WELSH COAST.—An occasional hoar frost is all that occurs here to remind us of winter, and even that of the feeblest kind, as will be gathered from the fact that Violets, Marie Louise and others are now plentiful, and have been since September, in the open garden near Barmouth. Last week I saw a fine basket of Chrysanthemums recently cut, and others growing and blooming freely in defiance of the elements, in the gardens at Tynycoed, Barmouth, Dr. H. Lloyd's. I also saw a fine specimen of Eucalyptus thriving well.—MAWDDOCH.

— THE GARDEN ORACLE.—We have received a copy of Mr. Shirley Hibberd's annual for 1890. Besides the usual tabulated and calendarial matter, it contains excellent selections of plants for cultivation, and lists of new plants. Several pages are devoted to the vegetable garden, commencing with reference to the Conference at Chiswick and enumerating the varieties selected there. Compact cultural notes are given on the different kinds of vegetables. The work is essentially useful and suitable alike for the gardener and amateur. It is published at 4, Ave Maria Lane, Paternoster Row.

— THE FLORISTS' LACED PINK.—A circular has been forwarded to us which states that a Committee has been formed with the object of establishing a National Pink Society, "to promote the cultivation of the Florists' Laced and Border Pinks." It is also proposed to hold Shows at the Royal Aquarium in June and July of the present year.

— WE have received from L'Horticulture Internationale Société Anonyme, Pare Leopold, Brussels, a flower and growth of a new winter-flowering Carnation, MADAME ARTHUR WAROCQUÉ, obtained from a sport of the well-known Souvenir de la Malmaison. The plant is of a sturdy dwarf-growing habit, does not exceed 12 inches in height. The flowers are large, well shaped, and of a brilliant red colour. They are produced very freely; five or six are open at one time. It is named after Madame Arthur Warocqué, a lady whose zeal and love for horticulture is well known in Belgium.

— THE WOLVERHAMPTON HORTICULTURAL SHOW AND FLORAL FETE is fixed for 15th, 16th, and 17th July next in the Public Park.

— TOMATO CULTURE was the title of a paper read by Mr. J. B. Riding before the members of the Ware and District Horticultural Mutual Improvement Society on Tuesday the 31st inst.

— GARDENING APPOINTMENT.—Mr. Henry Stride, late gardener to James Allen, Esq., Highfield House, Shepton Mallet, Somersetshire, has been appointed head gardener to L. J. Baines, Esq., Bawtry Hall, Yorkshire.

— MR. EDGAR NEWTON, glazing reformer of Hitchin, sends us a copy of his combined sheet almanack and memoranda form. It is, however, in twelve sheets, one for each month, and will be handy and useful in gardeners' offices and cottages.

— MANY will probably have learnt from the daily papers that the KING OF THE BELGIANS' PALACE AT LAEKEN, NEAR BRUSSELS, has been recently destroyed by fire. Fortunately, however, the handsome conservatory and collection of specimen Orange trees were saved.

— WE are requested to state that the date of the RUGBY CHRYSANTHEMUM SHOW FOR 1890 has been altered from November 12th and 13th already announced to November 19th and 20th, to avoid clashing with the Show of the Birmingham Society fixed for the first-mentioned dates.

— I FIND that LUCULIA GRATISSIMA lasts longer in a cut state if the leaves and stems are put into a large pan of tepid water about a couple of hours before they are wanted, care being taken that the flowers are not immersed, as they quickly become discoloured.—J. SMITH, *Henbury Hill*.

— FRUIT CULTURE.—The Drapers' Company of the City of London have sent to the Fruiterers' Company a donation of £105 towards the fund initiated by Sir James Whitehead, Bart., the late Lord Mayor, who is the Master of the Guild, for the promotion of fruit culture in our homesteads and cottage gardens.

— ON page 561 of the *Journal of Horticulture* for 26th inst. is a paragraph on BULLFINCHES by "T. A. C.," wherein is given a recipe for a winter dressing for small fruit trees. It would be a great benefit to your readers if "T. A. C." would kindly give the proportions of each ingredient used in the dressing.—GEO. WARE.

— UPON December 31st last, MESSRS. KELWAY & SON of Langport, entertained the whole of their employés at dinner. The chair was taken by Mr. W. Kelway, and a very pleasant evening was spent. Several appropriate speeches graced the occasion, songs, recitations, and instrumental music being also provided.

— THE RAINFALL AT CUCKFIELD, MID-SUSSEX, for December was 1.64 inch, being 1.23 inch under the average. The heaviest fall was 0.37 inch on the 22nd, rain falling on sixteen days. Total fall for the year 28.42 inches, 2.49 inches under the average of the past nine years. Highest temperature, 53° on the 22nd; lowest ditto, 20° on 12th; mean day temperature 43°; mean night ditto 39°; mean temperature 41°, being 2° above the average of seven years.—R. INGLIS.

— THE annual meeting of the READING AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION was held at the "British Workman" on Monday, January 6th, when a large number of members attended. Letters apologising for absence were read from the President (W. J. Palmer, Esq., J.P.) and Mr. Jas. Legg. Mr. Wm. Lees occupied the chair. The report of the Committee for the past year was read by the Hon. Sec., Mr. Jas. Pound, jun., and also a financial statement, which was highly satisfactory, there being a balance in hand of £17 12s. The officers were re-elected, and a committee appointed for the ensuing season. It is proposed to establish a library of works of horticulture for the use of the members.

— SIR JOHN T. D. LLEWELYN, BART.—All horticulturists, and many besides, will rejoice in the honour that has been conferred on this gentleman. As a country squire none could be held in higher esteem than he, where he is known best—in South Wales. A flying visit to his beautifully situated residence at Penllergare, impressed us with his devotion to his garden—his Orchids, Primulas, Auriculas, seedling Indian Rhododendrons in thousands, all being objects of his fostering care. The specimen Conifers, Rhododendrons, and other shrubs in the pleasure grounds, the wild Fern-clad banks, the kitchen garden sheltered with divisional hedges, all linger in the memory, and not less so the delightful reception the owner accorded his visitors. All friends whom we met, regardless of creed or political colour, had a good word to say for Mr. Llewelyn, and we offer to the new baronet our sincere congratulations.

— THE Annual Friendly Dinner of the Members of the GARDENERS' ROYAL BENEVOLENT INSTITUTION and their friends will take place, as usual, at Simpson's, 101, Strand, on Thursday, the 16th inst., after the annual meeting, when Edmund Yates, Esq. (*The World*) will preside. In order to ensure the comfort and pleasure of the company, the Stewards, Messrs. Webber, Monro, Dickson and Baker, have arranged that no tickets be issued after Monday, the 13th inst. The musical arrangements will be under the management of Miss Mary Belval.

— SOME remarkable examples of home-grown Liliiums have been brought under our notice by Messrs. Collins Bros. & Gabriel. From single bulbs planted less than two years ago large clumps of six or more well developed bulbs have been produced. The Liliiums were grown in the nursery of the firm at Hampton, the soil being a loam of medium quality, but a dressing of fresh cow manure was placed 6 inches below the bulbs prior to planting, and it is to this that their great vigour and unusual development is attributed. The variety is speciosum (lanceifolium) rubrum cruentum.

— STEALING GRAPES.—Mr. H. Balderson, Corner Hall, Hemel Hempstead, a member of the Royal Horticultural Society's Fruit Committee, recently had about 50 lbs. of Grapes stolen from his vinery, and two men charged with the offence have been sentenced to six months' imprisonment with hard labour. The members of the Fruit Committee seem to be much troubled with regard to their garden products, for it is only a short time since Mr. Blackmore prosecuted a man for stealing Pears.

— ON Monday, December 30th, the employés of MESSRS. J. R. PEARSON & SONS, Chilwell Nurseries and the Seed Warehouse, Nottingham, held their first annual social tea party and concert, when over one hundred sat down and enjoyed the repast provided by Mrs. A. H. Pearson, and who also accompanied the various performers during the evening. Songs, recitations, and several appropriate speeches quickly passed the time away, and the utmost cordiality prevailed. Votes of thanks were passed to the Messrs. Pearson for the kind interest they have always taken in any steps for the mutual improvement of their workmen. Mr. C. E. Pearson in reply said that it gave great pleasure to meet so many there, and anything his partner or he could do for them would not only be a duty but a pleasure. He hoped that there would always be the same good feeling existing between them, and in conclusion wished all a happy and prosperous new year.

— WE learn with regret that MR. WILLIAM H. BAXTER, who succeeded his father, and who for more than forty years has been associated with the Oxford Botanic Garden and the University Parks, is now incapacitated by infirmity for the performance of his duties. We understand that for some time past Mr. Baxter's impaired vision has occasioned considerable concern to his family and friends, and our readers will fully share with us the sympathy we feel for him in his affliction after being for so long a period so honourably connected with horticulture. We are glad to announce that the University authorities have marked their appreciation of his long and faithful services by a decree of Convocation, authorising the curators of the University chest to pay him annually the sum of £60, and this is supplemented by equal sums of £20, contributed by the curators of the Botanic Garden and those of the Parks. We cordially trust that Mr. Baxter may live to enjoy for many years his well-earned pension.

POTATOES.

PERHAPS a few words on last season's experience with Potatoes may not come amiss to some of your readers, especially just now when catalogues are being distributed from nursery and seed establishments.

In what glowing terms do they describe the varieties that are to prove such a boon to mankind. Disease-proof, disease-resisting, such enormous crops from so few pounds of seed, such cooking qualities—nothing that is good appears to be forgotten. To say that a certain Potato is disease-proof, is, in my opinion, a bold statement to make. No matter how sound the stock may have been, I doubt if there exists a variety which is not liable to the murrain, any more than there is any human being who is not liable to any malady common to mankind. I grew seven varieties last season, and only the following will be retained:—

Sharpe's Duke of Albany.—This did not crop heavily, but the quality was such that my master said he had never eaten a better Potato. We used it as a second early. It was not disease-proof, but I shall plant it freely this coming season.

Stourbridge Glory.—Not disease-proof, but it is the best late Potato I have grown. It did not crop heavily, but, like Duke of Albany, the quality made up for all deficit.

Snowdrop, though a good Potato, will be planted sparingly, on account of its taking the disease so readily.

Magnum Bonum.—This still holds its own as being a fair cropper and of good quality, though not disease-proof.

It seems at the present time that quantity and size are more valued than quality and a fair crop; indeed the tendency of the age seems to be to get everything as big as possible, but I cannot regard bulk as the standard of excellence in Potatoes.—J. M., *North Aston*.

THE ROSARIANS' YEAR BOOK.

MR. D'OMBRAIN says in his brief preface to the issue of this work for 1890, that though his "little craft is not so hulky as some of its predecessors, yet may prove that, like the old Spanish galleons of former days, she carries a valuable freight in a small space"—a little mixing of genders, perhaps, but the craft is well laden, and is not so small as to need the smallest apology. Sixty-seven pages of well printed letterpress is surely sufficient, especially when we find this so good, and varying as it does from grave to gay. Besides the Captain's contributions on Mr. R. N. G. Baker and his triumphs, and the season's review, Mr. C. E. Fraser discourses on Rose-growing in the Mauritius, the Rev. H. Temple Frere contributes "Notes by an Old Fogey" on the Roses of past days, Mr. Alexander Hill Grey sends "jottings" such as only he could jot—readable, amusing, yet not devoid of useful hints—Mr. John Haikness defends the Manetti as a stock, and gives his reasons, adducing also supporting testimony in its favour. Mr. George Paul tells which he has found the best autumn Roses; Mr. T. W. Girdlestone descants on decorative Roses, and amongst others names three "which no one need fear to plant boldly in groups—Hon. Edith Giffard, Madame Lambard, and Marie Van Houtte." The closing chapter is, as usual, on the "Weather of the Rose Year" by Mr. E. Mawley—a subject which few could treat so interestingly. We have only further to mention that the work contains an admirable portrait of Mr. Baker, and that Messrs. Bence & Sons, Old Bailey, London, and Derby, are the publishers.

LONG NAMES.

THE Secretary of the R.H.S., as quoted in your last (page 10), has many sympathisers in his lamentation over Rose nomenclature. It is earnestly to be hoped that what he writes will be attended to. No Rose ought over to have more than two names. At the same time it may be remarked that the Rose public, to a certain extent, has the remedy in its own hands. Judges will hardly demur at a title cut short, and even French families will be played out at last. The British public has a way of its own in dealing with such difficulties. Just as printers will make sense out of copy submitted to them, not always to the satisfaction of the writer, so if names are not English they have to become such. What is the history of the "Bull and Mouth" in the City? It commemorates the taking of Boulogne harbour in the reign of Henry VIII. Henri Quatre at another time made sense, though hardly appropriate, as Angry Cat, and when his master brought home the new mare Desdemona, the groom at once recognised in her name Thursday morning. Sailors are great hands at this, witness "Hirondelle," Iron Devil; "Bellerophon," Billy Ruffian. Dean Swift derived "Ostler" from Oat stealer, and "breeches" from bear-rieches, but that perhaps was a little far-fetched. I think it is Dean Hole who has introduced us to Senna Tea Vaisse, and Glory to thee, John, or Die John, as may be preferred. I myself can add another, met with only the other day, which is a case, however, rather of lengthening than of shortening. The well-known Niphotos is Greek for the snowy one; this is more often called Niphétus, or Niphéter, from which the transition has been rapid to St. Peter. Perhaps a unique instance of a Rose being canonised. There are saints, however, that deserve it less.—A. C.

DRESSING ROSES.

As no one has replied to my friend Mr. Pemberton's letter in last week's Journal, and as I believe it is calculated to do considerable injury to the cause for which I know he is as anxious as anyone—the

well-being of the Rose and of the National, I do not think it ought to pass unnoticed. May I not ask my good friend whether it is not a very unusual thing, when a motion has been put forward by the Committee of any Society, that any member of that Committee should consider himself absolved from his allegiance so far as to find fault with that for which, even though he were not present, he is responsible? However, let that pass.

If I understand Mr. Pemberton's contention aright, it is that (1) dressing is necessary in the case of some Roses, but that it is difficult to ascertain where the dressing oversteps the limits of the manipulation. Allow me to say that when the subject was discussed Mr. Pemberton's name was mentioned with this adjunct. No one could object to the dressing which he gives his Roses, and admiration was expressed at the skilful way in which he made them display their charms to the best perfection, and such dressing the rules of the Society acknowledge to be fair. (2), He seems to think it would be impossible to distinguish when a Rose was overdressed. This is one of those things which sound very well in theory, but which practice very soon demolishes. When you see a Marie Baumann so treated as to resemble in form and outline an A. K. Williams, when you have a La France with all its outside petals turned back, or a Madame de Watteville made into an imbricated flower, or a box of Teas with the centre standing up erect, and the outside petals lying flat on the board, there can be no doubt as to how that has arisen, and it is practices such as these which the new clause condemns. I think Mr. Pemberton must recollect some Roses at the Crystal Palace Show which were glaring examples of this overdressing. I believe that the object is to make the Rose look large, and that this rage for size is at the bottom of all the mischief.

But the strangest part of Mr. Pemberton's letter is that wherein he infers that the disqualification extends to the box, and not to the bloom only, and that the decision is to be left to some other authority than that of the judges, whereas it is with them that the decision is specially designed to rest; indeed it simply amounts to this, that in a box the one "rule in method of judging" would meet the case. The judges go through the boxes where points are to be considered, and they discard amongst the bad blooms those that they consider overdressed, and as in ordinary judging they give no statement as to which Roses they consider bad or good, no more will they be called upon to declare which blooms they consider overdressed. Mr. Pemberton is too experienced a judge to require any help from others, and I think most Rose-growers would be satisfied that he would as readily discard the overdressed Rose as any one of them.

After all, the flagrant cases in which this practice has been adopted are very few, and the object of the Committee in adopting the rule was to prevent its spreading; and now that it has been condemned I know that those who used to do it will cheerfully submit to the rules, and I hope that others may be deterred from following their example; and so far from fearing that the rule will occasion any interruption of that peace and goodwill which has marked our exhibitions, I believe that it will tend to the more honest and truthful exhibition of the Rose.—D., *Deal*.

I ALSO was unfortunately unable to attend the annual meeting of the National Rose Society, probably from the same reason as Mr. Pemberton; so I have delayed a week, hoping that someone who was present would answer his letter.

I am quite of his opinion that dressing is often beneficial and desirable, and sometimes necessary; everything seems to turn on the words of the new rule, "so as to alter their character." As to Souvenir de la Malmaison, I never to the best of my recollection saw, or expected to see, this Rose in Mr. Pemberton's magnificent stands; nor do I think, if he does show it, that it will make any odds how he treats it. Beauty of Waltham I can never get of the Marie Baumann shape at all, and it would take a very clever artist to make my specimens look anything like it; but Mr. Pemberton's grand culture does bring it more of this form, and I believe this fact is duly acknowledged and recognised. Madame Willermoz is, to my mind, the Rose to take as an example when speaking of dressing; for, if the strong temptation to turn down the outer petals is yielded to, there is no doubt that the natural character of the Rose is altered, though I cannot help confessing that to my eyes it is altered for the better.

Mr. Pemberton asks on what evidence are we to decide that such an alleged alteration of character is the result of dressing; but surely he knows as well, or better, than anyone. Even if no creases are visible in the petals, drawing the bloom lightly through the hand from beneath will cause the turned down petals to spring back to their former places.

Rule IX has always seemed to me undesirable; but it is not new, was not (I think) altered at the last meeting, has never to my knowledge been made use of, and will, I hope, remain a dead letter.

I would like to add a note as to Rosa laxa. I should by no means find it an advantage, as the introducer seems to think, to have stocks which do not grow in September. I do a great deal of budding in that month, and a considerable and most useful amount of rebudding takes place at that time of stocks whose first buds have failed.—W. R. RAILLEM.

CLIVIAS.

A FULL historical and descriptive article on the Clivias was published in this Journal, page 290, April 11th, 1889, in the course of which reference was made to a group in Messrs. Laing & Sons' Nursery, Forest

Hill. We are now enabled, by the courtesy of the firm named, to give an illustration of the group in question (fig. 5), which conveys an accurate idea of the decorative value of such plants.

perhaps seven years old, and it may be expected that the progeny of this and some other varieties will constitute a fine strain. Mrs. Laing is another of the same character, rather lighter in colour, but with exce-

FIG. 5.—CLIVIAS AT FOREST HILL.

One of the most conspicuous in the group was John Laing, with an umbel over a foot in diameter, containing twenty-two flowers, each $3\frac{1}{2}$ inches across; the divisions of the corolla broad, rounded, rich deep orange red, the centre creamy yellow. The plant was a strong one,

lently formed flowers; this was certificated a year or two since at the Regent's Park Royal Botanic Society's Show, and at the Crystal Palace. For several years past seedling Clivias have been raised at Forest Hill, and there are now hundreds of young plants in various stages, many

having now flowered. In about three years, if the plants are grown strongly, flowers are produced, but their best characters are not seen until they are five or six years old, and if in the meantime they bear a crop of seed it often weakens them to such an extent that the flowers are greatly deteriorated for a season or two. Out of a list of twenty-nine named varieties the following were the best in flower when the illustration was prepared, besides those already described. Orange Perfection, rich clear orange, well formed flowers; sulphurea, pale sulphur tint, compact truss, very distinct; Purity, orange red with a light centre; delicatissima, a large flowered variety of a soft orange tint; salmonea, a pale but clear salmon coloured variety; aurantiaca compacta, very free compact trusses, medium sized, good shaped, orange tinted flowers; Brilliant and Glow, both of high colour and excellent habit.

WANTED, A PUBLIC HALL FOR HORTICULTURE.

ON November 13th, 1888, a meeting of exhibitors and others interested in the work of the Royal Horticultural Society was held in the Council Chamber at Victoria Street to consider the expediency of any further occupation by the Society of the Drill Hall in Westminster. The meeting was of a satisfactory character both as regards numbers and the character of the persons present, for all present were workers in the concern, and any decision arrived at by such a meeting was felt by all to be sufficient for the immediate purpose. Acting on a conviction that I believed was shared by many, I made a definite declaration to the effect that the Drill Hall had proved unsuitable for the Society's purpose, and might with advantage be vacated at the close of the first year's tenancy. Having moved a resolution to this effect, Mr. Harry Veitch sprang a mine beneath my feet by stating that the Society could not legally hold floral meetings in the offices in Victoria Street, because anything in the nature of an exhibition was forbidden by the terms of the tenancy. The show of hands placed myself and my seconder in a minority of six. I have had such a run of good luck in carrying proposals that it was an enlivening change to be so completely beaten, but, like the compliant one that Butler sets forth in a suppositious case, I was "of the same opinion still," and to this hour I sigh for a place of meeting in which the flowers can be seen, and to which the public will resort to admire them.

Immediately after that meeting I proposed to friends interested in the affairs of the Society the desirability and possibility of obtaining a hall of our own for our meetings, and from that day to this I have occasionally discussed the matter, but quite rarely have I met with any encouragement, for the dread question always appears to block the way—How is the thing to be paid for? The question of primary importance is as to the need for a place of meeting that will be under our own control, and if not absolutely, at least in some part, the property of the Society, or of some corporation operating in harmony with it, and with a view to mutual interests for the public good. The thing having been talked about vaguely—as must happen in such a case—it appears to me in the nature of a duty to place before the horticultural public an outline of the thing that appears to me to be wanted, and of the means that appear to me suitable to bring it into being.

We want a hall for horticulture. It should be in a central position, convenient for access from leading roads and railways, and the construction should adapt it for flower shows, dinners, and other festivals, committee meetings, offices, and perhaps a general mart or exchange for miscellaneous business, as, for example, the display of plants for sale, the accommodation of trading firms for meeting customers, and for housing samples, models, drawings, and other materials required in business transactions in connection with agricultural and horticultural industries. There would be needful two or three (or more) well-lighted rooms adapted for public meetings, in addition to one spacious and noble hall, lighted in the way of a picture gallery, with orchestral platform and such other necessary features as would render it complete for the convenience of flower shows and festivals. Should the idea take shape it will grow as the plan is developed, and it should be comprehensive as a place of resort for horticulturists, who only need some such centre of operations to assemble in thousands where, as the case now stands, the habitues meet only in scores, and fresh faces are rarely seen. Country gentlemen, participating in the pleasures of the London season, would make a place in the list of things to be done of such an attraction as the hall would offer them, provided only the thing obtained success commensurate with the purpose in view.

One of my friends who has heard of my proposals has made a public offer of a subscription towards the project. As a thing to be initiated by eleemosynary contributions it should have no help from me, and I cannot imagine that many of my friends, to whom from time to time I have spoken on the subject, would put their hands to anything of that kind. There is only one foundation proper for a horticultural hall, and that is the commercial foundation. It must pay its way, or prove itself a mockery, a delusion, and a snare. I have not attempted any estimate of the amount of capital that would be required, but not having in view a cheap shanty or a bad imitation of a railway terminus, a considerable sum would have to be invested, and business must be looked for to ensure reasonable returns. The £100 per annum now being paid by R.H.S. for occupation of the Drill Hall ought not to be taken into account in this connection. I may be outvoted any number of times, but I feel sure that were a door to open leading to something better

and within the Society's means, the exodus would be speedy and unanimous. The Society is growing, and should grow. If it can pay £100 now for a year's accommodation, the day should be near when it could as easily pay a thousand. It is now, what it has not been for fully thirty years, a horticultural society; and the public are now taking a new interest in its work, and are daily more and more disposed to assist it, as is ever the case with a good thing that inspires confidence. The activities of the horticulturists carry them to all the ends of the earth for places of festivity and business. There may be a good side to the discursive system that fixes an exhibition in this spot and a dinner in that, but a recognised and generally acceptable central home would be an incalculable advantage to horticulture at large in the metropolis, and many sources of income would arise for a central hall that could afford accommodation for exhibitions, dinners, public meetings, and official correspondence for various institutions, both of London and the provinces.

This letter is not to be regarded either as a prospectus or a preliminary to any distinct business proposition. The subject has been lightly discussed in an erratic way, and the time appears to have arrived when I should give something like definite expression to my views that I may obtain the sympathy and aid of practical men in formulating a plan should opinion tend favourably that way. For the present it is with an idea that I should be quite content to see carried out independent altogether of any interest, sentimental or commercial, I may be supposed to have in it. I am fully occupied and happy in my work, and in no haste to make a mountain for the pleasure of piling a cairn on its summit.—SHIRLEY HIBBERD.

FLOWER CULTURE FOR PROFIT.

TEA ROSES.

AFTER about eight years' experience in marketing surplus produce I have arrived at the conclusion that nothing pays so well as Tea and Noisette Roses, and were I in a position to do as I please at least three houses would be devoted to them; as it is, they have largely to be grown in connection with various other plants, and not unfrequently the Roses are at a disadvantage accordingly. What they require and merit is plenty of room and light, with a moderate amount of heat, and if either of these conditions are withheld the growth is liable to become weak, mildewed, and insect-infested, the flowers as a consequence being few and poor in quality. Undoubtedly Tea Roses on their own roots are by far the best, either for planting in beds or for pot culture, but as these cannot often be purchased the would-be successful grower must perforce raise his own stock of plants. Luckily this is by no means a difficult matter. The first proceeding should be to purchase at once not less than three strong plants in pots, each of the selected varieties; these, when received, ought to be turned out of their pots and examined. Some perhaps will be found with few roots, drainage clogged, and the soil generally in a sour state, while a few—the minority I am afraid—may be in a healthy semi-rootbound state. The former should have the old drainage, and about half of the soil carefully picked away from the roots, and be repotted, using much the same size pots they were previously in, these being clean and well drained, and a compost consisting of three parts of good turfy loam to one of leaf soil or old Mushroom bed manure, sharp sand being freely added. The root-bound plants ought to be given a moderate shift, using soil as just advised, and potting rather firmly. All should then be placed in a light forcing house, and will be all the better for being partially plunged in a fairly brisk bottom heat. This should promote a free floriferous growth, and the more blooms there are the greater the stock of suitable cuttings.

Soon after the blooms have been cut, with about half of the shoot attached, the lower half will be fit for making into cuttings, being firm, yet not too hard. Take each off with a "heel," or very thin portion of old wood attached, and either insert singly in 2-inch pots, or else dibble a number into boxes just deep enough to admit of a square or squares of close-fitting glass being laid over without pressing upon the Rose foliage underneath. A loamy soil with plenty of sharp sand added is most suitable for cuttings, and these should be firmly fixed, taking care that they press against the bottom of the holes made with a blunt dibber. The cuttings should have the benefit of a fairly brisk bottom heat, and be kept closely covered with glass, sunshine being carefully excluded. Thus treated they strike root in a very short time, and the first important detail is mastered. In many instances cuttings may be obtained from various home-grown plants, but if a good stock of strong own-rooted plants are desired the propagating should be persevered with as early in the year as possible. We are invariably more successful with cuttings in March and early in April than subsequently, or when the sun has gained greater power.

Many succeed in striking Tea Roses only to spoil the plants later on. Once rooted they must be kept growing strongly, any check in the earlier stages of growth causing them to become stunted and useless. Instead, therefore, of leaving the cuttings

in boxes or small pots till they are badly root-bound, the former should be early potted off singly into 3-inch pots, and the latter shifted into 5-inch pots, all being kept growing in a moist heat, such for instance as a Cucumber, Melon, or Tomato house. On no account should these plants be allowed to flower while being prepared for late autumn and winter flowering, the wisest plan being to pinch out the buds whenever they show; also carefully keep them clear of dry hot shelves and the hot-water pipes, otherwise red spider may effect a lodgment and quickly ruin the plants. When the houses are becoming overgrown with Cucumber and Melons, or say about the middle of May, room ought to be found for the young Tea Roses on a light staging in a moderately warm greenhouse, where they must be kept clear of the other occupants, syringed once or twice in a day, and otherwise well attended. By this time they will have become established in their pots, and before they are root-bound should be given another shift, this time into 8-inch pots, or slightly larger if extra strong. Thus liberally treated they will soon throw up strong shoots or suckers from the base of the stems, and it is these suckers that give own-root plants such a decided advantage over any worked on stocks. We have frequently succeeded in raising plants that need yet another shift by midsummer, and this is always given. In each and every case clean well-drained pots should be used, and if there is but little fibre in the loam add more leaf soil and old Mushroom bed manure as well as charcoal freely.

Innumerable Tea Roses in pots, both old and young plants, are ruined by being too much exposed to all weathers in the open air. Only during the hottest and driest portion of the year, or say July, August, and the early part of September, should they be stood in a sunny sheltered spot, being housed before the pots become saturated and the plants badly mildewed. In reality, they are best kept under glass altogether, especially in the colder districts and where the rainfall is heavy. The greatest pains should be taken to keep worms out of the pots, the latter being set on a hard ash bottom, ashes also being the best material for covering the pots.

During the winter a light warm house, the temperature of which seldom falls below 50° during the night, and is maintained from 55° to 60° in the daytime, is the best position for Tea Roses in pots during the flowering period, cold currents of air being excluded as much as possible. They will succeed fairly well in a higher temperature, but the blooms are much smaller and the plants are liable to fail more quickly than is the case when less hard forced. Plants in a vigorous state may well be allowed to flower late in the autumn and any time during the winter, but as a rule the best supplies will be cut during the spring months and till open air Roses are available. Quite young plants are most given to push up strong branching suckers, and it is the latter that produce the greatest profusion of fine buds or blooms. They ought never to be kept dry at the roots, and if the pots are well filled with roots liquid manure of some kind, though not too strong, should be given frequently. When once a good stock of plants is raised abundance of good cuttings will be available every spring, and it is advisable to raise a number of fresh plants annually, the more weakly or exhausted old plants being either planted out against a sunny wall or thrown away.

All old plants after their serviceable period is over, or say early in July, may well be attended to at the roots. In some cases much of the unoccupied soil may be picked away and the plants returned to pots of much the same size they previously occupied, while others much root-bound should be given a shift. At the same time most of them ought to be lightly pruned, the aim being to cause the plants to push out strong growths early in the summer, and this if kept from flowering will be of good service during the forcing season. Varieties that do well in pots are Catherine Mermet, The Bride, Niphetos, Madame Falcot, Souvenir d'un Ami, Rubens, Isabella Sprunt, Marie Van Houtte, Alba Rosea, Comtesse de Nadaillac, Anna Ollivier, Madame Lambard, and Hon. Edith Gifford. The relative values of these will be given shortly, and also additional remarks upon Tea Roses trained over roofs and otherwise.—M. H.

POINSETTIAS AT MARSTON.

At the present time these make a fine display in the Marston Gardens, represented as they are by large numbers of well-grown plants, crowned with their bright-coloured showy bracts, far above the average in size. The somewhat low-roofed stove, a compartment of which is occupied with them, does not display them to the best advantage for inspection; but a portion of the stock, arranged in the most roomy fernery, lends a brightness unknown to this structure at any other period of the year. They look surprisingly well among the Ferns, their bold heads being better displayed than any other arrangement can afford. Two distinct varieties are noticed, the one at its best at the time of my visit being much earlier than the deep scarlet form generally

grown; the earlier one, too forms much the neatest break, and is the most effective. In growing the two an advantage is gained in the length of time the display can be maintained, and their value is greatly enhanced where they are used largely for room and dinner-table decoration, as is the case at Marston at this season. No flowers create greater admiration than well-grown Poinsettias when judiciously used on the dinner table for evening parties, and if care is taken to place them in warm water they can be used for two or three consecutive terms by change of design without becoming monotonous.

The whole of the plants are alike healthy and vigorous, though not possessing a great length of stem, and were furnished almost to the pots with leaves, a sufficient indication of perfect health. The summer-struck stock bears single stems and bracts, older plants being represented by several, and on one in particular I noticed a single stem carrying two fine heads. Their late summer and autumn treatment this year was cool, for I am told that for some time previous to being housed they had no protection from the elements, or rather only what little the walls of the pit wherein they stood provided, until the beginning of October. After they were taken indoors they were subjected to a dry airy atmosphere, and their present condition bears ample testimony to the suitable treatment bestowed upon them.—VISITOR.

THE NATIONAL CHRYSANTHEMUM SOCIETY.

A MEETING of the General Committee of the above Society was held in Anderton's Hotel, Fleet Street, on Monday, January 6th, at 7 P.M., R. Ballantine, Esq., in the chair, a good number of members being present. The minutes of the last meeting having been duly read and confirmed, Mr. Holmes stated, with regard to the Judges appointed for the Centenary Exhibition next November, that Mr. J. Douglas having a prior engagement could not accept the appointment, and Messrs. Barron and Roberts were also unable to attend; the following reserve Judges were therefore invited, and had accepted—namely, Messrs. Harry Turner, W. Wildsmith, and G. Miles. The Hon. Secretary also announced with deep regret the death of a respected member of the Committee, Mr. W. Blake, which took place on December 26th. For a number of years he was a regular attendant at the meetings, and had taken considerable interest in the proceedings. Mr. Holmes proposed, and Mr. Addison seconded, a vote of sympathy with the widow and family, which was supported by several members, and carried unanimously.

The dates of the early and late shows for the next season were then fixed for September 10th and 11th, 1890, and January 7th and 8th, 1891, Messrs. G. Gordon and R. Allan being appointed the Judges for Chrysanthemums. A schedule was prepared for the classes to be provided at the Royal Aquarium Show on October 15th and 16th, 1890, and the Hon. Secretary was authorised to expend £20 in prizes arranged on the same basis as at the November Show, the classes being as follow:—Twenty-four Japanese in not less than twelve varieties; twelve Japanese distinct; six Japanese, distinct (amateurs); six blooms, white, one variety; six blooms, yellow, one variety; six blooms of any colour except yellow and white, one variety; twelve Pompons, not less than eight varieties, in bunches, three trusses to form a bunch; and six Pompons, distinct (amateurs). A hearty vote of thanks was accorded to the members who acted as Stewards at the recent successful annual dinner. A resolution was adopted with regard to the medals. Eighteen Fellows and members were elected, making a total of 691. The Guildford, Stamford, Isle of Thanet, and Auckland (New Zealand) Societies were admitted into affiliation; and Mr. Drain was elected on the General Committee in the place of the late Mr. Blake. It was announced that Messrs. Castle and Gordon had made some arrangements for a Conference at the Show on January 8th, when Mr. Kipling had promised to read a paper on "Are Chrysanthemums Wanted at Midwinter?" and several questions would also be proposed for discussion.

THE NEW CATALOGUE.—Mr. Holmes stated that it was proposed to issue a new edition of the Catalogue during the present year, and it was desirable that the Committee, Messrs. Lewis Castle, George Gordon, and C. Harman Payne, should proceed with the work. As a permanent Committee he did not think they required any special authorisation, but as it would necessitate the expenditure of a large sum of money it was perhaps desirable to bring the matter before the General Committee. He remarked that the 1888 Catalogue had sold well, and would yield a profit; he therefore supposed there would not be two opinions respecting the desirability of continuing the work. It was then proposed, seconded, and carried, that the matter be referred to the Catalogue Committee to proceed with as rapidly as convenient.

CHRYSANTHEMUM LADY BLANCHE.

UNDER this name Mr. Stevens of Putney has grown a number of plants this year, the blooms of which were of the greatest value and in large demand for wreath-making and decorative purposes at Christmas and subsequently. Other late sorts were grown, but not one of them

was so fresh and floriferous as Lady Blanche. It is a Japanese variety with medium-sized flattish blooms with slightly curved clear white florets. The plants were not topped at any time, and made natural breaks about 18 inches from the pot, and the terminal buds were thinned. After Christmas hundreds of blooms were as fresh as blooms could be, and were being cut and sold daily. Plants of the same character would have made many a gardener's heart rejoice if he could have had them for cutting from during the festive season. Mr. Stevens regards this as by far the most useful late Chrysanthemum he has grown, and he thinks he has tried most of them. It is not an exhibition variety.—J. W.

KINGSTON AND SURBITON CHRYSANTHEMUM SOCIETY.

Most persons will be pleased to hear that this Society, which may justly be termed the pioneer of large cut bloom classes and Chrysanthemum groups in the south of England, is in a much better financial position than could be said of it in 1888, when, owing to adverse circumstances the Committee were only able to show a balance on the right side of £1 18s. 10d., whereas after the last Exhibition (1889), something over £65 will be carried forward. This will enable the Committee to improve their schedule of prizes somewhat, perhaps by adding to some of the prizes, and making other classes hitherto not included.—E. M.

CHRYSANTHEMUM BOULE DE NEIGE.

This variety is indispensable for blooming at Christmas. The blooms are borne in profusion on dwarf bush plants in 6 and 7-inch pots. This size pot is quite large enough, as it is not a tall grower. The flowers are of the purest white.

CHRYSANTHEMUM MOONLIGHT.

The flowers from crown buds and terminals differ considerably in many varieties, but in no instance that I have noticed is this variability more marked than in the case of the Japanese Moonlight. Those from crown buds are remarkably close, the florets incurving, so as to render the bloom almost as round as a ball, and it is not often they attain an exhibition size, solidity usually being outweighed by more bold open flowers. There is naturally very much less substance in the bloom obtained from terminals, but they are far more beautiful. We had a number of both kinds of blooms for Christmas, but the terminal flowers were the most valued. The outer florets of the latter are of good length and nearly straight, while the inner ones incurve prettily without being formal, and an elegant flower, such as ladies delight to wear, is the result. Moonlight is of rather straggling growth and not very floriferous, but it is one of the best for affording a few superior blooms towards midwinter.—W. I.

FORCED LILY OF THE VALLEY.

We send you a few spikes of our forced Lily of the Valley (Berlin crowns). They have been in great demand here the last fortnight along with Roman Hyacinths for dinner table decoration, and on mossy banks for a concert and a ball. They have been highly valued and admired.

As other gardeners like myself have not a specially prepared pit with a hot-water tank to force this plant in, perhaps the plan we adopt may be worth a corner in your valued paper. A hotbed of leaves and stable litter was prepared, turning the material a few times to let off the rank heat. When making up the bed was well trodden, and a two-light frame put on. Previously the crowns were planted thickly and firmly in boxes 2 feet long, 15 inches wide, and 4 inches deep, stood on an outside border exposed to all weathers and frequently watered. On the 14th November we had the boxes placed in the hotbed (1000 crowns), covering the crowns about 2 inches with old leaf soil. By the aid of a stick thrust in the bed we keep a careful watch daily, giving air when too hot, and covering the lights in cold weather. For a week the mats were kept on day and night, with a little ventilation to let off steam. When we saw the first blooms beginning to open, and taking advantage of a mild day, we shifted all the boxes to a light house having a temperature of 50° to 55°, and during two or three sunny days it rose to 75°. Early changing from frame to house is important. The plants suffer a slight check taken from the bottom heat, the all-important aid to start dormant life into activity at this time of year, but the check is slight. I noticed the first flower die on a few early spikes, but the bulk showed no change, and we began cutting on the 18th of December foliage and flower as natural and developed as when growing outside in June. We filled twelve pots with crowns and placed them in the same bed, but strange to say they are a failure; only two or three spikes came up in each pot, and I am positive we did not lose twenty crowns of the 1000 in boxes.—T. A. TODD, Sandridge Park, Bromley, Kent.

[The Lilies received are as fine as could be desired.]

GOOD VEGETABLES.—I should like to add a few more to the list already given by "J. L. B." on page 554 in last volume. In Broccoli he left out Michaelmas White, which is very far in advance of Walcheren, grows more compact, and is of better flavour. Cauliflowers Sutton's Favourite and Autumn Mammoth are two excellent Cauliflowers. Peas, Veitch's Perfection, one of the oldest, but still one as a main crop it is very hard to surpass. Duke of Albany and Sutton's

Satisfaction are two good Peas; Omega is good as a late variety. I gathered several dishes of them the last week in October. Of Potatoes, Sutton's Seedling and Abundance are favourites.—W. F.

HARDY FRUIT GARDEN.

REMARKS ON PLANTING.—There is a right and a wrong way in doing anything connected with fruit culture, and too often the inexperienced hit upon the latter much more readily than they do the former. Deep planting is the mistake most commonly made, and a very costly blunder it proves. It does sometimes do away with the necessity for stakes, but that is the only point in its favour, while there are several very important reasons why deep planting should be avoided. The most profitable trees and bushes are those kept rooting near the surface, but if the principal roots are buried deeply at the outset nothing short of lifting and replanting will bring them to the desired position and cause the formation of the requisite root fibres. Roots have a natural tendency to strike downwards, and it is only by planting near the surface, occasional root-pruning when the trees are young, and mulchings of manure or leaf soil, that they can be prevented from getting to undesired depths. It should be borne in mind that in very many positions, and especially near garden walls, the original depth of soil is being constantly added to; and it may be trees planted shallow at the outset may yet eventually have their collars far too deeply buried. Trenched soil in particular is apt to sink considerably and unevenly, and if in a moderately dry state at planting time this should be firmly trampled and made as level as possible. In any case it is advisable to plant slightly above the ordinary level, this being absolutely necessary where the land is naturally heavy, rich, and cold. In some few instances it may be a good plan to pave the intended site of a choice border, say just above the subsoil, with either a good layer of stones, brick ends, or mortar rubbish, this to a certain extent keeping the surface soil drier and warmer, and also checks a downward root-action. As a rule, however, there is little need for this, the better plan being to plant high and to favour the surface roots as much as possible later on. Ordinary garden soil, unless for some time previously occupied by fruit trees or bushes, usually suits young fruit trees better than a rich compost, though fresh loam, turfy or otherwise, and burnt soil and rubbish, may often be added to the former with advantage, a good sprinkling of half-inch bones also acting beneficially for several years. Soil already exhausted of much of its fertility ought to be largely removed and a rich loamy compost, and with which burnt soil, charred rubbish, and bones are freely incorporated, substituted. This relates more especially to the choicer wall trees, trenching old sites in the open, adding fresh soil to the shallow holes made for the trees and bushes, being all that can be afforded in most places. In planting, whether the lower tier of roots shall be spread out flatly and evenly from 4 inches to 6 inches below the surface, must depend upon the quantity or depth of roots each tree is furnished with; but in any case the upper roots may well be spread out fully 6 inches above the ordinary level. If the soil is heavy, lumpy, or rather too moist the least that can be done is to well surround the roots with fresh compost, making this rather firm. It must not be omitted that all broken ends of roots should be cleanly cut off and very long straggling roots shortened, the former facilitating heating, the latter causing the formation of more root fibres. Every root ought to be spread out to its full length separately and in a horizontal position, the reverse practice—viz., bundling them together into a hole too small for their reception, being particularly objectionable. Trees in the open should be properly staked, but those against walls must not be secured too closely till such times as the soil has settled, or otherwise they will be "hung." Watering-in ought not to be necessary, there being plenty of moisture in the soil, but a mulching of strawy manure, or, better still, half rotten leaves, may well be given, this preventing any ill effects from severe frosts.

FRUIT FORCING.

PEACHES AND NECTARINES.—*Early Forced*.—In the earliest house the trees are in flower. When fully expanded the night temperature may be maintained at 50° to 55°, the latter only when the nights are mild, 55° by day as a maximum in severe weather by artificial means when the sky is overcast, 65° by day from sun heat, and if the air be mild a few degrees (5°) more may be allowed. Syringing at this dull time must cease, but damping the floor and border may be practised in the morning and early afternoon on bright days. Lose no opportunity of ventilating freely when external conditions are favourable, and when the pollen is ripe choose the warmest and driest part of the day for aiding its distribution by shaking the trees or trellis, or taking a camel-hair brush or feather and gently applying the pollen to the stigma of each flower. If there be a deficiency of pollen of any variety, and there sometimes is of the large-flowered varieties, including the earliest, as Alexander, Hales' Early, Early York, Early Alfred, and Early Grosse Mignonne, it may be taken from those varieties that afford it abundantly, the small-flowered varieties having that characteristic, as Royal

George in Peaches and Elruga in Nectarines, Nectarine pollen being equally effective, if not more so, for the artificial impregnation of Peach blooms and *vice versa*. The outside border must be protected with litter or some other protective material, the inside border not being neglected for water.

Second Early Forced House.—The house containing trees to afford ripe fruit early in June should now be closed, damping the trees and house two or three times a day, turning the heat on by day for an hour or two in the morning, but not so as to exceed 50° by artificial means, allowing it to rise to 65° with sun heat and free ventilation. It will suffice if frost be excluded at night. The borders must be brought into a thoroughly moist state by repeated waterings and the outside border protected with litter, but not of a depth to heat violently. A gentle warmth of not more than 60° to 65° will do no harm, but more heat is hurtful. All that is wanted is a covering to prevent chill from frost and snow.

Late Houses.—These should be put into order forthwith, and if any trees are swelling the buds more rapidly (which is not the case where the roof lights have been removed) than is desired, a covering of mats over the lights will prevent the temperature being raised by sun heat to a prejudicial degree, retarding the flowering considerably. From our latest house the roof lights were not removed until late in December (as the buds were less developed than usual, and with a dry air the wood ripens up even after the leaves have fallen through the evaporation), and they will not be replaced until the necessity of the buds showing colour indicated need of protection.

MELONS.—Sow seed of approved varieties at once for the first crop. They may either be sown singly in 3-inch pots, or a dozen or more may be placed round the edge of a 6-inch pot, to be afterwards potted off singly into 3-inch pots. In either case the pots should be about two-thirds filled with soil, covering the seed about half an inch deep, plunging the pots in a bottom heat of 80°. Good fibrous loam and leaf soil in equal proportions gently pressed down will form a porous compost for the young rootlets, it being important for this early sowing that the pots be efficiently drained. It is of the greatest importance that the seedlings be kept near to the glass. Blenheim Orange and Read's Scarlet-flesh may be mentioned as good in the scarlet-fleshed section, and Hero of Lockinge and Longleaf Perfection are first-rate as a green and white flesh respectively. Ripe fruit from a sowing made now may be expected at the close of April or early May. A temperature of 65° to 70° night, and 70° to 75° day is suitable.

CUCUMBERS.—Sow now for planting next month in pits or frames heated by fermenting materials, which should be in process of sweetening for making up the beds. If no convenience exists for raising the plants a bed of fermenting materials should be made up forthwith, the seed to be sown as soon as the bed affords a suitable temperature—70° to 75°. Plants from this sowing will be available for house planting to afford a late spring and early summer supply of fruit. We only grow two named varieties—viz., Telegraph and Cardiff Castle, but there are many other good varieties.

Plants in Houses.—Young plants just coming into bearing should not be overcropped, and assist them by removing staminate blossoms as they appear. Plants in bearing will require to be cut over about once a week, preferably twice, removing all weakly and exhausted growths, reserving as much of the young growths as can have space for expansion of its foliage, overcrowding tending more than anything to disaster, inasmuch as it must end in denuding the plants of a large extent of foliage. Stop the shoots at one or two joints beyond the fruit, but young plants should be allowed more freedom, avoiding overcrowding. The temperature by night should be 65° to 70°, 70° to 75° by day, with a rise of 10° or more from sun heat, admitting a little air at 80° if the external air be moderately warm and soft, but if cold and sharp it is better to allow the temperature to advance a little higher than admit too much cold air even when the sun is powerful. A little flowers of sulphur dusted on the walls and pipes, also foliage, is a good preventive of mildew and red spider, and quicklime rubbed well into any part of the stems affected with canker will subdue it. The floor and other available surfaces should be damped in the morning and early afternoon.

CHERRY HOUSE.—The house being closed last month as advised fire heat may now be applied so as to maintain a temperature by artificial means of not more than 40° at night, and 45° in the day, advancing 10° by sun heat, ventilating at 50°, and closing at that point. Ventilate very freely in mild weather, and avoid hasty treatment in the early stages of growth. See that trees in pots or tubs are not neglected for water, and sprinkle the trees and house occasionally in the morning and afternoon in bright weather.

Strawberries in Pots.—Do not push the plants too rapidly in severe weather, 50° to 55° will be sufficient at night for those that were started last month, and 60° to 65° by day, but it is always well to err on the safe side, therefore 5° less in the absence of sun, the weather being cold, is advisable. More plants should be introduced to shelves in Peach houses or vineries started about this time. The pots should have the drainage rectified if necessary, the surface of the soil freed of moss or other material, and the pots washed. A surface dressing may be given of rich material, as a pinch between the finger and thumb of Amies', Clay's, Jensen's, Beeson's, Thomson's, &c., manure, stirring the surface lightly. If space some fine manure mixed with steamed bonemeal and soot, a quart each to a bushel of the manure, and well incorporated, will prove advantageous and a great encourager of surface roots. Suitable varieties for introducing now are Noble, La Grosse Sucrée, Vicomtesse Hericart de Thury, Sir Joseph Paxton, and President.

THE FLOWER GARDEN.

Tender Bedding Plants.—December and January are rather trying months, not a few summer bedding plants being lost about this time. November appeared to be very favourable to the well-being of autumn-struck Zonal Pelargoniums, these, thanks to clear weather and abundance of genial air, becoming strong, well rooted, and floriferous. Pans and pots of Henry Jacoby are quite gay with bloom, and others are also nearly as free flowering. All ought still to be kept on the dry side, this being especially necessary where the plants are stored in frames, pits, and but slightly heated houses, and dead and dying leaves closely removed, the aim being to keep them in a hardy semi-dormant state till the days become longer and warmer. Heliotropes that have flowered in pots ought now be kept somewhat dry at the roots, in order to well ripen the wood prior to cutting back slightly and starting in heat early in February. Such plants should give abundance of cuttings. Late-struck cuttings of these, as well as Ageratums, ought to be kept steadily growing; nor should Lobelias and Verbenas be dried off at the roots, but if placed on shelves in a cool house and given plenty of air in mild weather they will continue to grow slowly and strongly, abundance of good cuttings being obtainable when the propagating time arrives. Kept near the hot-water pipes the growth soon becomes wiry, dirty, and valueless. Calceolarias, Violas, Gazanias, and Echeveria secunda glauca, all of which are usually wintered in frames, ought to be well protected from severe frosts, the sides as well as the glass of the frames being enclosed by a bank of dry litter, or by mats and litter, yet they should receive abundance of light and air whenever this can safely be given. Unduly coddled they become yellow and weakly, and never grow into such fine plants as result from more intelligent treatment. The comparatively hardy Hollyhocks, Carnations, Pinks, Phloxes, Pentstemons, and Antirrhinums stored in cold frames and pits may well be protected from severe frosts. Not much water is needed, though they ought not to become very dry at the roots, and certainly must have plenty of air whenever the state of the outer atmosphere permits. The very tender Iresines, Coleuses, and Alternantheras are easily kept on shelves in a stove temperature, but if the attempt is made to winter them in a warm greenhouse, then must very little water be given them. Tuberous Begonias are easily injured by frosts, and any lifted stored in shallow boxes and placed in a cool shed must, whenever a severe frost is anticipated, be covered with mats or old sacks. Nor must the roots or tubers of Dahlias or Salvia patens be much exposed. A covering of dry soil prevents shrivelling, and mats, or even a good covering of paper, will ward off frosts. When these, Begonias, and Callas are stored under greenhouse stages drip is the greatest enemy. Unless something is done to ward off this a considerable portion of the stock may either start prematurely into growth or decay quickly.

THE BEE-KEEPER.

HINTS TO BEGINNERS.

DURING the past season I have had many inquiries from beginners, and have visited most of their apiaries. The queries were varied, but in nine cases out of ten the owners were disappointed, the bees had died, and no honey was obtained. The year 1889 was an unpropitious one in which to begin bee-keeping. The cold spring following so untoward an autumn as that of 1888 many hives were rendered useless or almost so, and the short but early summer prevented any but extra strong hives gathering surplus, unless it was in some favoured and sheltered spot. The summer of 1888 was unfavourable for queens mating, and many of the hives purchased by beginners had aged or unfertilised queens, neither of which will give satisfaction or profit. The most important thing in a hive is a healthy, youthful, fertilised queen, and it is a most important thing for a beginner to make sure he is procuring young queens.

To insure this he ought to deal with trustworthy men only. If a swarm of the current year let it be an after one rather than a prime one, and let the bargain be that the queen is fertilised before the price is paid, or if more than one, that all be. This will, as a rule, be satisfactory the following year. If these swarms are early ones they may gather a surplus the same season, especially in districts where Heather abounds if it grows upon the right soil or rocks. If the beginner start with prime swarms, and the season is a fine one he may secure a considerable quantity of honey, but on no account should these aged queens be kept to form stocks for the following season. Steps should be taken to secure young queens for the number of stocks expected to be kept, but on no account should

imported queens be purchased, to a greater number than one or two, and where there is one hive only have none at all until the beginner has gained some experience.

Although I do not agree in all "A Hallamshire Bee-keeper" says, still his advice on the question of raising queens is good, and the bee-keeper who follows it will be the gainer. Nearly forty years ago I discovered that bees, queens and drones, that were retarded in hatching, were more or less deformed externally, the wings being the first to suffer, the other members also being more or less defective, but never turned my thoughts to the probability that the internal organs were similarly affected. About the same date I discovered that when there was much pollen in the hive, such as is the case when the bees are at the Heather, they were liable to abdominal distension, and that they wintered better on pure sugar syrup, although the latter was better for breeding purposes. "A Hallamshire Bee-keeper" is therefore in error when he says, "It was Heddon who started the pollen theory." Long before Heddon was heard of in this country, and perhaps before he kept bees, I observed and recorded the fact that when bees had access to pollen, such as I have stated above, bees were liable to abdominal distension, but not to what I term dysentery, this latter being happily more rare than the various forms of abdominal distension, and is perhaps not what the Americans speak of. I quite agree with "A Hallamshire Bee-keeper" that a chill to queens while in their cells will injure them permanently; but how does it come that, under the natural system of swarming, the queen cells are in different stages just at the time when a prime swarm leaves, which reduces the temperature greatly in the hive? yet we have not experienced that the queens were impaired thereby. Doubtless the bees cluster round the royal cells, and so locate the heat necessary for the full development of the queens; so that although the general temperature of the hive is reduced, that of the non-conducting waxen cells of the queens is not. I have not had a case of dysentery amongst my bees for years, and yet I form my next year's stocks from nuclei by dividing a natural swarmed hive into as many as a dozen nuclei, about the ninth day after the prime swarm.

SELECTING ROYAL CELLS

It is impossible to tell by appearance of the cell whether the queen will be a good one or not. I have had queens raised in common worker cells, and have had them frequently built upon the face of the comb, that did not show the slightest projection, and these queens turned out profitable. When I have a choice of royal cells I prefer those that show a good deal of red between the sealing and cell proper, rejecting those of a white appearance, believing them to be defective from want of sufficient heat for their full development. While I am convinced that all bees suffer from too low a temperature while in the metamorphosing state, I cannot think that they will be seriously affected while the temperature they are exposed in is not under 60°, or even less. If "A Hallamshire Bee-keeper" can convince us to the contrary he will confer a favour on many besides—A LANARKSHIRE BEE-KEEPER.

(To be continued.)

BEEES ON THE NON-SWARMING SYSTEM.

LIKE "Felix," I am inclined to think that the non-swarming system is the best for a large yield of honey, especially in some localities where the honey harvest is over by the 15th of July, as is the case in our district. As soon as we hear the reapers in the meadows we know the honey season is near its end. Under these conditions to keep our bees from swarming is the best, but in localities where white Clover abounds and the honey harvest is much longer, the swarming system may answer very well. In both systems one thing is absolutely essential—to have our hives strong enough to take advantage of the first flow of honey, and this may be done by having the stocks strong in the autumn by driven bees, by uniting after the honey harvest is past, and in spring if found weak by joining to nuclei in spring, and by giving plenty of good syrup to last through the winter well into spring. On the non-swarming system great care must be taken with strong stocks in spring, when many young bees are coming forth and honey is coming in freely, by giving plenty of room just as they want it, and by judiciously supplying supers. If honey is abundant, as soon as one crate of sections is

half completed put on one more, and so on possibly a fourth. The bee-keeper must use his judgment so as to have most of them completed. If run honey is wanted the doubling system answers well, and if the extractor is kept at work when the honey flow is on a good harvest may be had, but where time is precious as the bars are sealed they may be taken out and extracted at pleasure, empty ones taking their places, but it must be remembered in all cases that sealed honey is much the best, both in quality and as food or medicine, as the case may be. If the above hints are followed out, in most cases the swarming fever will be prevented. This is the course that I have pursued, and have rarely failed.

A bee-keeping friend of mine who follows the non-swarming plan, and has succeeded well, told me some time ago whenever he tried to prevent his bees swarming he had in no case failed. Some bee-keepers have tried the non-swarming system, and failed simply because they did not attend to the wants of the bees in time to prevent the desire to swarm. We must prevent the swarming impulse, and we shall mostly succeed; however, such has been the experience of—A HOWDENSIRE BEE-KEEPER.

BEE QUERIES.

PERHAPS you will kindly allow me, through your columns, to put a few queries before your correspondent, "Lanarkshire Bee-keeper," regarding his cheap hive, instructions about which appeared in the issue of January 10th, 1889. I should be obliged if he would inform me (a novice) whether 14 $\frac{1}{2}$ or 14 $\frac{3}{4}$ inches is the correct length of the top bars in connection with the above hive? How is the doorway to the hive constructed? What depth ought the division to be for the sections, and is the same depth suitable for small supers? Which kind of wood is recommended for making the hives?—J. D. L., Northumberland.

TRADE CATALOGUES RECEIVED.

G. Bunyard & Co., Maidstone.—*Catalogue of Vegetable and Flower Seeds.*

Armitage Bros., Nottingham.—*Catalogue of Vegetable and Flower Seeds.*

Harrison & Sons, Leicester.—*Seed Catalogue, 1890.*

John Peed & Sons, Roupell Park Nurseries, London.—*Catalogue of Seeds.*

William Barron & Sons, Elvaston.—*Catalogue of Forest Trees and Cover Plants.*

Barr & Son, 12, King Street, Covent Garden.—*Descriptive Catalogue of Seeds.*

E. P. Dixon & Sons, Hull.—*Catalogue of Garden and Farm Seeds.*

John Walker, 7 and 8, High Street, Thame, Oxon.—*Catalogue of Garden and Flower Seeds.*

✱ All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Address (Agriculture).—Messrs. Ballière, Tindall & Cox, King William Street, Strand, London, is the address you require.

Cryptomeria japonica (T. L.).—Thanks for specimens, but we do not think they are uncommon, at least in the south of England.

Fungus in Mushroom Beds (L. A. W.).—We suspect the peculiar growths had their origin in the manure and not in the soil, but if all the manure was from the same source and similarly prepared the fact that one bed should be free and another infested is a little mysterious.

French Marigolds (X. Y. Z.).—There are specially good selections of both the tall and the dwarf strains, and neither one nor the other can, as such, be relied on to produce the best exhibition flowers. You had better try both, and you might do worse than procure small packets of seed from two or three sources.

Scale on Palm Leaves (J. T.).—The leaves are infested with a kind of scale, and your best plan would be to sponge the leaves with soft soap and warm water, or a small brush may be necessary to remove them. Those sent are in such a bad state that you are not likely to succeed in restoring them to health; remove the worst, and cleanse the others thoroughly.

Raising Lettuce Plants (E. T. H.).—Are you certain the fault of the failure is not in the seed? Old seed is very uncertain in germination, and the plants that do appear from it are often so weak as to make poor (if any) progress. The soil in which the seeds germinate and the plants grow well outdoors ought to answer equally well for raising plants under glass. However, if the soil you use is not suitable mix equal parts of loam and leaf mould; then if a similar failure occurs you may be certain the cause is either in the seed or management, not in the soil.

Glass for Plant Houses (J. C.).—The sample of glass sent is quite unsuitable for plant houses. It is far too thick, and would exclude much of the light so requisite for plants in this country. Such glass is not used in the establishment you name for the roofs of plant houses, and the green-tinted glass is also being discarded even for the Fern houses. To expect plants to succeed in a constant state of semi-obscurity is unreasonable; they will grow for a time, but become attenuated and weakly. Light is essential to the solidification of the growth made, and what shade is needed from strong sunlight can be readily afforded by means of roller blinds.

Names of Plants (Adolescents).—You are quite right. There is much confusion in the methods of rendering plant names in catalogues, and if you peruse them all it is not surprising your "head's in a perfect whirl." The general rule with regard to terminations is that the generic names ending in "us," "a" or "um" require similar terminations to the adjectives employed as specific names, but there are exceptions to this too numerous to mention here, and the first point to be determined is the gender of the substantive, which in names of plants is the title of the genus, then the adjective should agree with that. Sometimes, however, old generic names are employed as specific names in new genera, then the old name retains its original form, and does not necessarily agree with the genus in its determinations. Latin adjectives ending in "is" have only two terminations—namely, "is" for masculine and feminine and "e" for neuter. Some generic names ending in "us" are however regarded as feminine, as *Quercus* for instance, and their specific names are written accordingly—viz., *Q. coccinea*, *Q. rubra*, &c. The subject will probably be explained more fully in an article upon plant nomenclature promised for an early number of this Journal.

Solanums (J. R. S.).—If you have only a window for the plants you had better not cut them back till early in April, then by the time fresh growths push the weather may be warm enough for their being placed in a very sheltered position outdoors, protecting them from frosts which may occur in May, and cutting winds. More than half the old soil should be removed from the roots after fresh growth starts, repotting firmly in good turfy loam, a sixth part of crumbled manure, and a tenth of wood ashes. The pots may be plunged just over their rims in a sunny border for the summer, standing them on smaller pots in the ground to prevent worms passing to the roots. They must be watered as needed, which will not be half so frequently as if the pots were exposed. Clear soot water is good for *Solanums* when the pots are filled with roots. Some persons plant them out towards the end of May, lifting carefully, and potting firmly in September, watering well, sprinkling the foliage, and letting the plants stand in the shade for a time for keeping the leaves fresh and inciting quick root action. We have seen fine plants grown in that way, but all persons do not succeed alike. You might try both methods, and so gain experience that might be useful to you in after years.

Planting Anemones and Ranunculi (M. R.).—Choose the first fine day when the soil works cleanly for planting your Anemones. They are best planted in the autumn, but will do now. Draw drills across the bed 2 inches deep and 5 or 6 inches apart, and plant the tubers 5 inches apart in the rows. For choice varieties a thin layer of sand scattered under and around each tuber will be useful. As soon as the bed is planted cover the tubers with sandy loam from a basket or wheelbarrow. Take care that the tubers are placed the right side up, by observing the side that has the old small fibres on it. That side place next to the bottom of the drill. When all are planted and covered up the right depth (2 inches) then level the surface with a garden rake. The soil and preparation of the bed you describe will suit them very well. *Ranunculi* will all probably succeed if you mulch the bed in the spring to keep it moist, but they prefer stronger soil. The season for planting is in the early spring, as soon as the most severe frosts have passed and the ground has become tolerably dry. Some time about the end of February or the first week in March, rake the surface of the bed in the morning of the day previous to that fixed upon for planting. Some recommend steeping the roots for twelve hours in water before planting, but we think this not necessary, except the planting season has been from some cause or other put off till the middle of April; then it may be useful. Supposing, then, that the weather is propitious, and all things prepared, commence by drawing with a hoe a drill across the end of the bed, $1\frac{1}{2}$ inch deep; if deeper the root will be weakened the succeeding year, by forming a kind of stem nearer the surface; and if shallower, the plants are more liable to be struck with drought. Plant the tubers, if large, 4 inches apart in

the row; if small, $3\frac{1}{2}$ inches will be a sufficient distance, and cover them with fine sand. This will cause the tubers, when they are taken up in July, to come out of the ground quite clean for keeping.

Peach Buds Falling (H. J. P.).—We are glad you have sent specimens of the shoots. You say "according to your idea the wood is everything that could be desired." We may say that the examples before us are very far from being so good as they should be. We consider them inferior—ill-fed and immature. This may be the result of overcropping, and possibly overcrowding. Be that as it may, trees if not furnished with better and stouter wood, with less pith, are not in a condition to be forced, though it is possible that if not forced, or only very gently excited so that the root action and sap movement are synchronous, the buds might be retained, and fair crops of fruit follow. We should take a good deal of the old soil from the roots and add fresh calcareous loam, making it firm, but not positively hard, mulch, cut out such weak, ill-fortified shoots as you have sent, and encourage the production of stouter growths, which should be thinly disposed throughout the season for insuring early and complete maturation. We should commence the border renovation and pruning at once. No doubt the trees by their previously heavy bearing have earned a season's rest.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*R. N. R., Youghal*).—The Pear is Winter Nelis. (*P. H. W.*).—Green Nonpareil. (*J. M., Isle of Man*).—The Apples are unknown to us. There is little doubt they are local and inferior to the best varieties in general cultivation.

COVENT GARDEN MARKET.—JANUARY 8TH.

BUSINESS has settled down to a quiet state again, and our Market being well supplied, prices are very easy. Good samples of Grapes are now coming shorter, but ordinary quantities are low priced.

AGRICULTURAL VITALITY.

THERE is no such thing as standing still in this world ; while life and strength hold we must go forward to meet the good and evil of life, always resolute to grapple with our difficulties, to rise superior to and overcome them. That some such feeling animates agriculturists as individuals and as a class we have no doubt, for we may certainly speak of agriculture as progressive and not stagnant. On every hand there are signs of intelligent progress, which betoken vitality, and which certainly point to a brighter decade than that which has just closed with the last of the eighties.

No doubt there are still many grave faults of practice and custom to correct. One of these is the show-yard gloss of cattle, sheep, and pigs. It is claimed that "mountains of fat" are no longer visible at agricultural shows, and we grant that the system is modified, but it is still wastefully in error. Take, for example, the Sandringham prize pen of South Down sheep at the Smithfield Christmas Cattle Show ; were they not seriously fattened to waste ? So, too, were several other pens. Christmas beasts always abound in butcher's waste, and the tendency to favour small breeds is fast growing. Go to any cattle mart now, and it will be found that small well finished animals invariably command more competition and a better sale than large coarse beasts. Various reasons have been given for this, but we think it is a clear case of a general preference for meat of high quality, hence the popularity of Devons and polled Scots. Kerries are also gradually making way for beef as well as milk, and the *Live Stock Journal* tells recently of a very remarkable carcase of beef being one of the Kerry heifers from Elsenham Hall, the depth and thickness of which in proportion to its length being phenomenal.

Early maturity in breeding has especial attention, and is bound to affect all breeds sooner or later. Keen competition is very apt to induce undue preference on the part of breeders for the development of beef rather than dairy points in a breed. Take the Herefords for example. In the improvement of these massive animals beef alone has been kept in view, and milk has been quite ignored. From a strictly economical point of view this is wrong, but the temptation to develop beef only in the "White Faces" was irresistible. We went through a large herd of them in Northamptonshire last autumn ; they were out on rich pasture, where they had been also regularly trough fed. Not one of them would be tied up, for they were just as ripe as Blackberries, and were being sent off to London at the rate of ten a week. Nobody could venture to generalise with such grand beasts before him, for there was evidently "money" in them, and a lot of it too. Can we wonder that the judges of Red Polls at Windsor should remind breeders of the importance of retaining the high milking qualities of this breed, in which the tendency to produce beef is so apparent also ?

This is a reminder that dairy farming is progressive also. Miss Amy Barron's recent lecture on the science of butter making in her native village of Borrowash, near Derby, abounds with useful hints and sound practical information, and is certainly worthy to rank with the exhaustive lecture on the same subject given by Dr. Voelcker a month or two ago. Butter factories are increasing, much to the benefit of local farmers, the latest announced being for the especial benefit of Sir Henry B. Meux's tenants, and is calculated to take the milk of 500 cows. The initial capital required for the building and management of such a factory is £4000. The prices guaranteed for milk are 5½d. per gallon for six

months, 6d. for two months, 7½d. for two months, and 8½d. for two months. These prices appear low in comparison with that paid to retailers of milk, but they are certain, and there is no risk of loss, no carting to railway stations, no delivery at long distances.

By all means let us push on the dairy farming, and everything else that tends to make us less dependant on corn growing. The Australian Wheat harvest is almost ended, and the calculated surplus of Wheat is a million quarters, which will not be held for a market, but will be sent to Europe and sold at any price. There may be a falling off in Wheat growing in the United States of America, but it must never be forgotten that Wheat is imported in considerable quantities into this country from nearly twenty other countries besides the United States. It is always coming, nothing can keep it back, and though farmers may wax eloquent upon the wrong done them by the people being fed below the cost of production, be very sure the people will not suffer their rulers to tax them to save the farmers.

WORK ON THE HOME FARM.

Poultry repay well now for especial attention. They suffer from exposure to cold, and are wrtched in the extreme upon a sodden muddy run. We have two fowl houses, one entirely enclosed by weather-boarded sides, with roosts and nests ; the other boarded at the ends and back, but the front facing the south has fine wire netting, with about 2 feet of the bottom only boarded. Here most of the fowls are fed, and they are induced to remain here on wet or snowy days by a fresh supply of fine dry ashes daily. There are plenty of low perches upon which some pass the greater part of the day, while others revel in the dust ; a Cabbage and a Mangold or two are placed in this feeding house frequently, and are much enjoyed. Eggs come freely, and are the best evidence of successful management.

Akin to this subject is the case of cows now. A warm, clean, cosy, yet well ventilated cow house is the best promoter of health and a full steady yield of milk. Roof ventilators such as we described a few weeks ago answer best, and there is no draught. When cows are kept in altogether they should have roomy quarters. We have seen them coupled for winter in stalls that were much too narrow, the poor animals not only being very uncomfortable, but getting in a most filthy condition. Altogether better is it to let cows have a little exercise on all fine days than to keep them constantly tied up. In the cow houses of the metropolis the cows are mere machines, kept only so long as they yield milk freely, and then at once passed on to the butcher. Such treatment is no guide for the home farmer ; he requires healthy animals for breeding as well as milking, and he cannot afford to use them up in a season or two. All the town milkman looks for in a cow is a big frame and a big bag, quality of milk or special breed is nothing to him. Mixed food and an occasional change should be given to all store cattle, and they should always have access to rock salt. Without a well-managed dietary they often fall off in condition now, and become very mangy. One can tell at a glance if beasts are well managed, but that is a matter that should not rest with the stockman, nor should it be possible for him to waste food ; weight, and measure, and close supervision are the best checks.

METEOROLOGICAL OBSERVATIONS.

REMARKS.

29th.—Dense fog till about 3 P.M., then fairly clear.
30th.—Cold and slightly foggy ; gas necessary from noon owing to high fog or smoke cloud.
31st.—Fog rendering gas necessary till noon, then cleared, and sunshine from 1 P.M.
1st.—Fog ; gas necessary till 12, then slight till evening, when it became dense again.
2nd.—Fair, but slightly foggy in the morning ; cloudy afternoon.
3rd.—Fog till 11 ; cloudy and damp till 4.30, then rain.
4th.—Dull and damp early ; fair day, with a little sunshine at noon.
Another very dull and rather cold week ; temperature not much above freezing point and no warm sunshine except on 4th.—G. J. SYMONS.

CONFERENCES.

NEVER before in the history of British horticulture have so many meetings been held for the discussion of special subjects as within the past four or five years, and the present has not been inaptly described as "an age of conferences," for the remarks above made are almost equally true respecting other trades and subjects of general importance. To solve a difficulty, to elucidate an obscure subject, or to afford a ready means of interchanging ideas upon an interesting and popular topic the form of meeting termed a conference is unequalled. As applied to horticulture our American cousins have taken the lead in arranging such meetings, and their success has amply justified the extension of what may be termed a system of mutual instruction. There are times when men become tired of reading, and seek for a more social form of gaining knowledge and spending their time usefully. Lectures have from the earliest time constituted a pleasing mode of conveying instruction, but there is something didactic or scholastic about this which renders it distasteful to some, and it is essentially unsatisfactory unless the implied superiority of the teacher is well maintained. For the unskilled in any profession or occupation it is most desirable, but experienced men often differ in their opinions and practice, and while seeking information themselves can often enlighten others upon difficult matters. In a conference the speakers and auditors are placed more upon an equality than in any other system; there is freedom for the expression of all opinions for or against certain methods or ideas—in fact it is really, or should be, a public conversation on a wide basis, organised with a view to the elaboration of some subject of special or general importance. The more this social feeling can be encouraged the greater freedom will there be in the expression of ideas, and this is what is required to render such gatherings serviceable in the highest degree. The more widely correct information upon any useful subject can be diffused the better it is for all concerned, and happily the old narrow views respecting the restriction of knowledge with regard to successes in horticulture are becoming obsolete. We find many of the most successful practitioners readily communicating their opinions and the results of a life's study to thousands through the medium of the press, and few indeed who in conversation with a brother gardener will not with pleasure relate the details of his best and most special work. There are many, however, quiet, observant, earnest men who have perfected themselves in their calling by close application, but who rarely or never attempt to shine in print, yet who have their minds filled with useful practical knowledge they willingly communicate when the opportunity offers. For such as these the social conferences advocated are specially adapted. The more ideas that can be brought under examination the better, and the benefit will fall mostly to those who are quickest at catching "notions," and the most skilful in executing them.

The reasons advanced appear to me conclusive that conferences on horticultural matters when properly conducted must prove advantageous in a more than ordinary degree. They interfere with no "vested interests," no one class of horticulturists is alone benefited, but all who desire to do so can profit by an interchange of ideas upon a favourite subject. Much, therefore, can be urged in support of such gatherings. The more they are increased in numbers the greater the advantage to the gardening community. There are no prizes to tempt the cupidity of individuals, or induce the envy and

other evil feelings which occasionally arise in the breasts of unsuccessful competitors, and it is impossible to imagine how the most pertinacious and exacting fault-finder can reasonably object to a combination of individuals for their common good when such a combination is also for the benefit of horticulture generally.

The best methods of arranging meetings of the character referred to may be worth a little consideration. As I have been concerned in the organisation of at least six London conferences on horticultural subjects, and as these have been considered satisfactory gatherings, and have collectively attracted something like a thousand persons, I may claim to have gained a little experience in the work. The ideas thus secured are here set forth for the assistance of those who may wish to arrange meetings of a similar character. In the first place it is necessary to avoid long papers, and this is a difficulty which is not easily dealt with. When anyone is invited to read a paper the tendency is to produce an exhaustive treatise, highly creditable to the writer and reader, valuable if printed, but scarcely adapted for the purpose of a conference. When the papers are long, however good they may be, the interest flags, and where there are so many points to consider few are remembered for remark afterwards, and, as a rule, long papers induce but little discussion. If it is desired to have one or two papers upon the subject to be examined they must be short, pithy, suggestive, reviewing disputed points, and calculated to encourage others to express their views either in opposition or agreement. It is also preferable where possible that such papers should be printed and circulated amongst those who intend to take part in the discussion before the meeting commences. When a paper is read some of the points are sure to be missed, whereas if it could be glanced through and passages marked they could be readily taken up subsequently. This was well shown at Hull recently, where printed slips of the papers were distributed in the meeting, and one of the most animated and prolonged discussions I have ever witnessed followed.

It is possible, however, to avoid papers altogether, and the result of an experiment tried at the National Chrysanthemum Society's Conference last week was so satisfactory that the plan might well be extended. Some of the American and other societies have long adopted the system of submitting questions upon particular subjects to the meeting, entrusting different individuals with the task of introducing each to the meeting, or they are submitted through the Chairman. The questions are published with the programmes of the meeting, and distributed amongst the members, so that all have an opportunity of thinking the subject out before it comes on for consideration. If the questions are carefully framed, so as to cover a good deal of debateable ground, there is no difficulty in obtaining discussion, and this is what is required—more talking and less reading—not one man's ideas, but those of as many persons as can be induced to express them.

One important matter in the regulation of the business is to secure a firm and impartial Chairman, who is well versed in the subject under consideration, and much of the success will depend upon the manner in which this indispensable official performs his duties. At the same time all those who engage in meetings of this kind should be prepared to accord generous attention to opposing views expressed in temperate language. Disputation and discussion are very different, and some persons rarely give utterance to a diversity of opinion without doing so in offensive terms or tone. It requires some judgment to determine where free, smart, but fair criticism ends and objectionable personality begins, and the fact is very few are qualified as racy critics, for the majority who assume that character lose sight of the special objects of these meetings, and seek only to vaunt their own opinion at the expense of others. One such individual, if he be not duly kept in bounds by the Chairman, is sufficient to defeat the purpose of the best planned gathering, or at least to deprive those present of all pleasure in the discussion, which is effectually checked when dominated by a dictatorial person. It is sometimes advisable to limit the time at

the disposal of each speaker to ten or fifteen minutes, but it is seldom that these periods are exceeded in an ordinary discussion, and it is perhaps better to leave the matter in the hands of the Chairman, who will be able to judge when the speaker is keeping to the subject under consideration, and contributing useful information.

Some minor matters need a little attention. For example, the room or building in which the Conference is held should not be too large; a moderate sized room well filled is far better than a spacious hall with a scattering of auditors. The necessary means of ventilation must, however, be provided, as a hot close atmosphere is not likely to have a very inspiring effect upon those present. The time and place chosen for the meeting must of course depend upon a variety of circumstances, but it may be stated in a general way that a conference upon any special horticultural subject should be arranged whenever possible in connection with an exhibition which would serve in some degree as an illustration of the topics dealt with. More interest would also be added to shows of all kinds, and their practical usefulness increased by such gatherings, whether for conferences or lectures. I remember well some years since when the National Rose Society held a provincial Show in the Sheffield Botanic Gardens, what a large company assembled in the afternoon to hear a lecture by Dean (then Canon) Hole, and how much more interest was imparted than the mere exhibition would have afforded. A lecture from a well known and recognised authority on a subject, or a conference of amateur and professional gardeners, might be arranged for nearly every one of the larger shows in the kingdom with little difficulty, and at an insignificant expense. With a good band nothing further should be needed to render really horticultural shows successful; country fêtes and galas, in which horticulture only plays a secondary part, are not included in this category.

The Royal Horticultural Society has done valuable work in instituting conferences and similar meetings, their record of the past seven or eight years being a varied one. In October, 1883, the National Apple Congress was held at Chiswick, but no papers were read, and there was no arrangement for public discussion. At the Orchid Conference, however, in May, 1885, several excellent papers were read, followed by a most interesting discussion. The National Pear Conference was held in October, 1885, but again no papers were read, though at the Primula Conference in April, 1886, several were submitted. The Orchid Nomenclature Conference at Liverpool, in June, 1886, was opened with a few remarks, and one paper was read; the discussion also was fairly good on this occasion. An Apple and Pear Conference took place at Chiswick in October, 1888, when a series of exhaustive papers was contributed, and the discussion also was spirited. The year 1889 was an exceptionally busy one in regard to Conferences, for the Society named arranged no less than three, one devoted to Roses in June, to vegetables in October (a remarkably successful meeting), and to Chrysanthemums in November, all being conducted on the same lines—namely, providing papers on special subjects, followed by discussion. For the present year Conferences on Daffodils, Carnations, and Ferns are also announced, so that the Council has evidently recognised the importance of this form of meeting, and may fairly claim to have done good work in their promotion.

The Fruit Conferences at the Crystal Palace in September and October, 1888, which led to the formation of the British Fruit Growers' Association, also attracted much attention, as did the meeting held in the same place in October, 1889, and a series of similar Conferences now being arranged for the present year, may be expected to yield similar results. The National Chrysanthemum Society has held several Conferences, that last week being in some respects the most satisfactory of all. Besides these various meetings of a similar character have been arranged at provincial towns, as at Sheffield, Leicester, and Hull, but these have been chiefly devoted to Chrysanthemums, and there is plenty of room for others.

Another and important form of mutual improvement which in recent years has been much extended consists in the institution of gardeners' societies in provincial towns, the principal object being to hold meetings for discussions on various subjects connected with practical gardening. The Paxton Societies in the north of England, notably at Leeds and Wakefield, have done good work in this way. There is also a Society in Nottingham which holds very interesting meetings. At Birmingham and Reading frequent gatherings occur during the winter at which papers are read. The Chiswick Gardeners' Mutual Improvement Association holds its meetings weekly from October to March in the Council Chamber of the Chiswick gardens, and an admirably diversified programme is provided every year. The rules of this Association are also brief and suitable for societies of a similar kind. After providing for the election of officers, &c., three or four rules referring to the regulation of business are so admirably adapted for their purpose that they are here reproduced for the guidance of any concerned in the formation of improvement associations. They are as follows:—
“That members wishing to read a paper shall submit the title of the same to the Secretary at least a month previous to the night on which it is to be read, so that it may be announced and members have an opportunity of preparing for it. That the time allowed to the reader or opening speaker do not exceed half an hour. Any extension of time may, however, be granted at the discretion of those present. That succeeding members be allowed ten minutes to speak, and that no member be allowed to speak twice until the others present have had an opportunity of speaking. That no discussion be allowed between two or more members, but that each shall address the chair and the meeting generally.”

These combinations for mutual advantage merit every encouragement. They promote an advance in knowledge and increase a social friendliness amongst those engaged in the same calling. We are occasionally told that this is not an age for sentiment, but if it is intended by that expression that the rush and rivalry of securing a living are to exclude all kindly feelings and generous recognition of other competitors, it can only be regarded as a pernicious doctrine emanating from grossly selfish minds. If civilisation and society offer any benefit to mankind it must consist mainly in mutual assistance, and this applies as much to societies of all kinds as to families and the state generally.—
LEWIS CASTLE.

BRITISH APPLE CULTURE.

KNOWING, as I do, the interest the *Journal of Horticulture* has taken in the cultivation of such fruits as are eligible for the supply of our home market, at the head of which I feel disposed to class Apples, I ask for space in your valuable columns for the following remarks.

I purchase what Apples we require for family use, and if I could get them conveniently I would only buy British grown ones. I get what I do buy from Jas. Lindsay & Son, the great fruit importers of Market Street, Edinburgh, and when I asked them why they did not deal in English and Scotch Apples, their reply was, “If the English and Scotch growers would pack them as the foreigners do we would do so. As they do pack them we can put a thousand barrels of foreign Apples through our hands quicker than we could put a tenth of the quantity of British.” Surely our home growers are not so destitute of resource as not to be able to meet a case like this. Machinery could make barrels as cheaply in Britain as in America or Germany, and they might copy the way the foreigner packs the Apples. To my taste there are no foreign Apples equal to good English ones for cooking. They are dry and lack the fine brisk acid taste of, say, Lord Suffield, Ecklinville Seedling, Hawthornden, Cellini, and others that might be named, and keeping off the true “Newton Pippin” from America, there are no foreign Apples for table use equal to Ribston Pippin and Cox's Orange Pippin. Many of the so-called dessert Apples from the Continent are dry, as in the case of Russets, and full of worm holes.

If the growers of Apples in such counties as Kent, Hereford, Gloucester, and some of the other best Apple-growing counties, would place their fruit packed as the Americans do theirs on rail, I could guarantee them a large sale in Scotland alone. Surely if the Americans, with their more expensive labour, can make

barrels, pack their fruit as they do, pay a commission on the other side of the Atlantic, freight, and another commission on this side, not to speak of two profits, if not three, ere they reach the consumer, the home grower could hold his own, seeing the foreigner is so handicapped.

Pass through any town in Britain, I might almost say village, and you will see in all the fruiterer's shops, as well as in those of grocers, barrels of Apples, and not one of them British. Surely this is not as it ought to be. We send hundreds of thousands of pounds of British money into nations that meet all the products of our industry with the most hostile tariffs. Will patriotism not arouse some grower to take the lead, and set an example that would induce others to follow?—WM. THOMSON, *Clovenfords*.

BEING much interested in Mr. J. Wright's comments, perhaps he will not object to my endorsing his trite remarks, at the same time adding a few notes. I agree that it is not the foreigner's fault that fruit of first class quality is not produced at home, and there can be no question about the failure of the Britisher in this respect. Living in this great Apple growing county of Herefordshire, I fully endorse the remark on page 23, "That weight for weight, the practically worthless and unsaleable home-grown Apples in good Apple years exceed the importations of handsome-looking, well sorted fruits that come from distant shores." It will always be the case, unless a radical change takes place, that the growers of high-class fruit will at any time be able to secure good prices, because those growers are comparatively few in number who grow only the best and carefully grade their goods before consigning to market. Packing, again, is done in the most slovenly manner, and in a way that would ruin the choicest fruit. Fruit trees are neglected in such a manner that good crops of fine fruit cannot be reasonably expected. If orchards were annually manured in the same way as other land from which crops are naturally looked for there would not be so many worn-out orchards in which the trees are comparatively young.

Many run away with the idea that fruit growing is an easy matter and certain to be remunerative. So it is remunerative, but only in the hands of those possessing knowledge, capital, and untiring perseverance, and then failures will occur which no human power can avert. I have not the least hesitation in stating that many will regret embarking on fruit growing. I know of more than one instance where a great amount of money has been expended by gentlemen, in such a manner that it is certain to never return, through the employment of incompetent men. If a capitalist goes in for fruit growing a competent man is a necessity to get successful results, which, taking one year with another, is certain when properly managed. Probably the greatest drawback in fruit culture is the "caterpillar plague." Last year the damage done was immense, and this year I fully expect an even worse attack unless something unforeseen occurs. Fruit trees, forest trees, and hedgerows are thickly studded with the eggs of the winter moth; and though we had a splendid autumn for fruit trees, ripening their wood, and perfecting the fruit buds, the outlook is decidedly gloomy. The person who can invent a certain remedy for this pest deserves a country's gratitude and a well filled pocket.

A good deal has been written about the Fruiterers' Company's efforts to promote improved methods of fruit culture, and I for one wish them every success in their plans whatever form they may take. Every method of improving the present low standard of home-grown hardy fruit deserves a welcome, because no Apples grown abroad can equal well grown samples produced in this country.—S. T. WRIGHT, *Glewston Court Gardens*.

SOME NOVELTIES.

PERHAPS a few lines regarding several varieties of Melons and vegetables grown in the past year may be of some use to those now thinking of preparing their seed orders. I will commence with Melons as the best of fruits raised from seed, and I consider a high class Melon when at its best as second to no fruit. Messrs. Henderson of New York sent me for trial their Delmonico Musk Melon, a large fruit most beautifully netted with pinky flesh, the skin being when ripe of a yellowish green tint (in fact the illustration of Triumph Melon in Messrs. Sutton's catalogue is an exact representation of Delmonico Melon, with the important exception that there is no green in the flesh as in Triumph, which is described and figured as a green flesh). The appearance of a well grown fruit is grand, and when cut the palate confirms the judgment of the eye. It is a very weakly grower at first, and it grew so spindly that I threw all my plants but two away, and those I planted in a corner of the house where nothing could grow well to live or die, not caring much which. However, they grew apace, although the growth is so thin one would hardly think it would

support large fruits, which it does. All the fruits were large and handsome, and I do not know a Melon I like better.

Albert Victor was sent out as a novelty, but it was no novelty to me, for a friend of mine grows a Melon exactly similar to it. It is of robust constitution, and the fruits are well netted and bright yellow when ripe. It keeps well—in fact is the best keeper I know—and has white flesh of good but not of the best quality. I can recommend it as a sort easily grown. Blenheim Orange and Hero of Lockinge are not novelties now, but are the most reliable of all Melons, the latter being far and away the best of the two. A seedling of mine, which Mr. Gilbert has dubbed Her Ladyship's Favourite, is to my mind the best Melon grown for quality and appearance, but of course every man likes his own chicken's best. I have heard of it being delicate, but Mr. Fisher of Boreham House, who grows it in the Melon house, and more largely in frames, finds it to be of robust growth.

Of Peas I will only mention Sharpe's Victory and Triumph, the former about 2½ feet high, bearing long pods of very deep colour with peas of good colour and quality; a useful Pea but not equal to some others. Triumph is a good all-round Pea, and I believe one of the best of the second earlies with large pods tightly filled with large peas, and the quality is good; I can strongly recommend this Pea to all. I must not forget William Hurst, which is so useful for early work, and I observed Mr. Iggulden found it equally useful for late sowing. It is far in advance of American Wonder. Some years ago I tried Dr. Hogg, and found it to be quite the best second early Pea for quality, the pods so packed with peas that there was a difficulty in opening them. I seldom see this Pea mentioned, the Giants being more fashionable, but I mean to return to it this year, which indeed I should have done before had I not been overburdened with such a number of different varieties in hand.

In Longpod Beans the greatest advance I have seen is Bunyard's Exhibition Longpod. I have found this to have very long pods of deep green colour, filled with beans from end to end tightly packed. I have always found these monster Beans very apt to have gaps in them and the pods more woolly substance than Beans; but here the proportion of pod is not great, and there are no gaps in the beans. It is the best Longpod I have grown for number of beans in pod and as a prolific bearer.

Of Dwarf and Runner Beans Ne Plus Ultra Dwarf is, I consider, the best of all French Beans—early, great cropper, fine Beans and high quality. Ne Plus Ultra Runner is the longest Bean grown, and is a fair cropper and the quality is good. It is very useful for exhibition purposes, but for general usefulness commend me to common Scarlet Runner.

Late Broccoli are very useful, and the latest of all is Gilbert's Victoria, which I found excellent in every way, and I had plenty to cut when all others were done with. Snowball Cauliflower is dwarf, very early indeed, and snow white. No better can be had for early work.

President Carnot Brussels Sprout is tall, bearing profusely firm and large sprouts of good quality, but I cannot say I consider it better than Sutton's Exhibition well grown.

Guerande Carrot is to be highly recommended. It is very similar to Sutton's Early Gem. I grew many nearly as thick as they were long. They are good for exhibition and of splendid quality, and a great weight can be grown in a given space. Sutton's Intermediate was an excellent companion to the above, the colour and shape being good.

Daniels' Masterpiece Cucumber I found a very shy bearer, but the fruits were magnificent, and I never knew a Cucumber carry such a heavy bloom. No better Cucumber could be grown for the exhibition table.

I have already given a description some time back of the varieties of Tomatoes I grew. It is sufficient to say Laxton's Open Air is best for outdoors; Volunteer, Golden Sunrise, Prelude (small), and Perfection for under glass.

Sutton's White Heart Cos Lettuce cannot easily be beaten for quality, long standing, and appearance, and amongst the Cabbage Lettuces I was extremely pleased with the fringed Early Ohio.

Laxton's No. 1 to succeed the Ashleaf, with Bouncer to follow on, together with Sutton's Satisfaction, will make a trio of Potatoes which I think can hardly be beaten.

I have a guilty feeling that the Editor's patience will be exhausted before he gets so far as this, so I will try to save this from the waste paper by concluding.—H. S. EASTY.

EUPHORBIA JACQUINIÆFLORA.

Few persons will be prepared to dispute the claims to beauty and usefulness which well-grown specimens of this fine old plant possess when their graceful drooping shoots are wreathed with

their neat yet brilliantly coloured scarlet flowers, shown off to perfection with a feathered edging of deep green leaves. At this time of the year, when sprays are in great demand, a single flowering shoot makes by itself a finished addition to a lady's dinner or ball dress, or when it is desirable to use a few white flowers as well. Lilies of the Valley or Roman Hyacinths irregularly fringed around the scarlet Euphorbia, with a few Fern fronds added, make a very effective and uncommon spray. For arranging in mixed groups of plants, when grown in 4 or 5-inch pots, carrying from one to three flowering shoots, they add a pleasing feature to such arrangements that cannot be obtained with any others flowering at the present time of the year.

Although Euphorbias are such deservedly popular favourites, they are neither grown so largely or so well as they should be; it is not unusual to find plants in anything but a thriving state by the time they approach the flowering stage. Having had plants under my charge at different places during the last dozen years, the opinion I have formed concerning the causes which often bring them into an unhealthy state may be worth recording. Here they are in an abbreviated form—too much root room, too much water, and too much peat. Those plants that are rooted during the spring months we flower in 5 and 6-inch pots, and by the time they are in flower the pots are crammed with roots, yet we have no difficulty in retaining their deep green leaves down to the rim of the pots till they have done flowering.

When the plants have made about an inch of young growth they are shaken out of the soil, the roots are trimmed back, and they are placed into the same sized pots; subsequently the strongest of them are shifted into 7-inch pots, and the remainder into 6-inch ones, and whenever potting is performed we always give small shifts. During the growing season when well established they should receive a good supply of water, but in autumn and winter we allow them to become drier at the roots than is good for most plants. Once get them into a sodden condition and they are certain to lose a great number of their leaves, and in some cases, to use a familiar term, "go off" at the collar, and I have noticed that the latter calamity occurs the most frequently to plants that are grown in a compost in which peat predominates, and when an unnecessary amount of root room is given. This not unfrequently happens to planted out specimens, and although the plant under notice is excellent for covering back walls in stoves or intermediate houses where they can receive a fair amount of light, yet great care should be exercised in watering, and the roots be restricted both as to depth and width and border. We often find that the simplest composts are the best, and after trying various mixtures for Euphorbias have found them succeed best in pure turfy loam, with a little sharp sand and charcoal added to bring the soil into that mechanical condition under which roots of all plants are the most rapidly produced. I would not, however, advise the use of loam alone in all cases, for the simple reason that loam differs so much in quality and texture, and it is not everyone who can obtain it in such fine quality as we are able to procure it here, being more inclined to be light than heavy, having a fair amount of fibre, and of a fine friable nature, in which so many kinds of plants produce roots abundantly. When the loam used is rather heavy an equal portion of good peat should be mixed with it, and in potting made the soil fairly firm.

When the plants have done flowering they may be either removed to a slightly cooler temperature or kept in the stove, and be kept dry at the roots, giving a little water occasionally till they have started into growth, then they should be shaken out and repotted. If large numbers of cuttings are wanted the plants should not be pruned back before being potted. Numerous side shoots will then be produced along the main branches; these can be taken off with a heel when they are 3 inches long, and the old plants pruned back to the required height; they will then send out fresh shoots and form good specimens. These old plants often produce a great number of shoots, and are very useful for cutting from. Young examples are, however, best for decorative purposes. When the whole stock of old plants is not required for another season the strongest should be selected for growing, and after being rested a month prune them, and take the cuttings from any not intended to be grown, and which of course will not require potting.

The cuttings that have been taken with a heel should have the cut ends dipped in a little powdered charcoal or dry sand to stop bleeding, and then inserted singly in thumb pots, a lump of good peat or turfy loam being placed at the bottom of the pot, the remainder filled with a mixture of half loam and half peat sifted through the half-inch sieve. When the cuttings are put in a little sand should be dropped into the hole made with the dibble, and the cutting passed into it and made firm, and receive a good watering through a fine rose. As soon as the soil has drained the pots are ready for placing under handlights, in propagating or Cucumber

and Melon houses, where they can have about 80° to 85°. They should receive daily attention to prevent moisture condensing on the leaves. As soon as condensed moisture is noticed inside the handlight it should be wiped dry, and a little air admitted for a short time, otherwise some of the young leaves will turn yellow and fall, and the cutting eventually rot at the collar. Given a good brisk bottom heat, and daily attention to the details above mentioned, cuttings of this much-esteemed winter-flowering plant will root almost as certainly as Crotons.—H. DUNKIN.

FREESIA REFRACTA ALBA.

THERE is an attractive group of Freesias at the present time in the greenhouse at Kew. Many of the plants above referred to are grown in large 24's, in which they have flowered successively for two years, merely receiving a top-dressing. For those requiring smaller plants, from eight to ten corms may be placed in 32's about the third week in July, using a compost of light loam two parts, leaf soil one part, and one part of well decayed horse droppings, with a mixture of sand. They should then be placed in a cold frame or pit. Plenty of air must be admitted, and on warm bright days the lights should be taken off to insure a dwarf sturdy growth. When growing freely they delight in abundance of water, and on no account should the soil be allowed to get dry during the growing or flowering period. An occasional supply of soot water and a top-dressing of fish manure will greatly assist them. Attention must also be given to staking, split bamboos being recommended for this purpose. If required to bloom as early as November they must be placed in a temperature ranging from 55° to 60° Fahr., but they are best brought on gradually, the flowers lasting much longer. If, as is the case at Kew, a second or even a third supply be grown the group can be renewed from time to time.

After flowering the usual method is to dry them off and store in bags, but this practice should not be followed. Better results will be obtained by allowing them to remain in their pots, gradually lessening the supply of water. In the following summer a top-dressing of the compost recommended should be given.—ALPHA.

GOOD VEGETABLES.

CHRISTMAS holidays are an excuse for most things, so perhaps you will allow me to plead them as an excuse for harking back to the admirable article under this heading, page 554. Your correspondent, "J. L. B.," is most kind in his advice to send early orders to the seedsman; happily that advice is not so much needed to-day as it was ten or fifteen years ago, when early orders were the exception, whereas from all good gardeners they are now the rule.

Would that it were possible to compress seed catalogues after the manner he indicates, the seedsman's lot would then be a (comparatively) happy one; but much as I deplore the bewildering list of varieties I fear that the seedsman has no alternative but to publish them, and although much has been done in the way of eliminating the names of varieties which have been proved to be synonymous with others, and in discarding those which have been superseded by newer and improved kinds, there still remains work to be done.

The seedsman is not, however, entirely to blame in the matter. Take, for instance, Peas which, as your correspondent says, are a difficult class. Is it to the seedsman's interest to grow thirty to forty kinds if he could induce his customers to be content with ten? Surely the smaller number would be easier to keep true and cheaper to grow in large bulks, than the small lots required of many of the kinds. But there are many reasons why he cannot reduce the list as much as he would like. Firstly, he has still to put in names which are synonymous because there still exist, in remote parishes, gardeners who are so sure that Sangster's No. 1 and Daniel O'Rourke are different Peas, that they year by year have a pint of each, out of the same sack, and come and tell you which was the earlier. Then one has the gardener who every year orders thirteen quarts of Peas in thirteen different varieties for his year's supply. I do admire that man, how he manages to secure a succession of Peas for table is always beyond my comprehension, but I suppose he does.

Then, again, we have the broad fact that tastes differ—one man will eat nothing but sweet peas which he usually calls "Marrow-fats," he cares nothing for early round peas, but will wait until his favourites are ready, and then wants them as long as he can have them. A second dislikes that class of Peas, and enjoys a class like Supreme, which has what I call a beany flavour. I knew a gentleman who cared for no other Pea but Champion of England. Again, we have the fact that certain kinds succeed better than others in a fixed locality, and as the seedsman has to send his goods north,

south, east, and west he must grow what his various customers require. It is, however, a mistake to suppose that he recommends kinds "which are least profitable to the gardener" purposely; on the contrary, he grows them in his trial ground alongside old standard sorts. Sown under the same conditions and at the same time, and consequently so far as that soil or locality is concerned he is probably in a better position to judge of their merits than the man who sows them as a succession crop in a garden. I do not know whether "J. L. B." has grown Duke of Albany, but if it crops with him as it does here he must make an exception in its favour when condemning exhibition Peas.

Finally, to show how opinions vary, I should take exception to one name contained in the small list of Peas (only five), page 556, for I consider Hundredfold one of the poorest Peas we grow; and what should we do without such old friends as Kentish Invicta, Little Gem, and Veitch's Perfection, which in my judgment is the best of all Peas except Prince of Wales, or the newer acquaintances American Wonder, Duke of Albany, and Stratagem. Potatoes would supply matter for a long article. Practical gardeners can best help in reducing the excessive number of names in vegetables by seconding the work of the R.H.S., and giving publicity to names which in their opinion are synonymous, and also by indicating their locality and soil when they give selections, so that the reader may know if he is under similar conditions.—A. H. PEARSON.

CATTLEYA LODDIGESII.

This is an excellent Orchid, and does very well with us in the plant stove with a mixed collection of plants. We have two plants of this variety. One is grown in a pot in a compost of fibry peat, with a liberal addition of charcoal. This plant each year makes two and three new growths about a foot in length, and regularly opens its beautiful flowers—occasionally two, but more frequently three on a spike—early in December. The flowers are very lasting, as one plant when in flower is in the house for a month; after being returned to the stove the flowers remain quite fresh for a fortnight longer. The other piece is grown on a raft, but the growth is much shorter and weaker, the flowers consequently are much smaller, I therefore think it requires pot culture. During the growing season the plants are watered when dry the same as others. When growth is completed only sufficient is applied to keep the growths plump until the flowering period is past. Colour of flowers, sepals, and petals pale rose tinged with lilac, with light rose lip marked with yellow. Native of Brazil.

CYMBIDIUM EBURNEUM.

This also does well in the stove. Perhaps I ought to state the temperature during the winter months ranges from 60° to 70°; during very cold weather it frequently runs down to 55° by morning, and owing to the close proximity of a high wall it seldom reaches 70° during the day, never exceeding that figure. During the summer months it ranges from 65° to 80°. *Cymbidium eburneum* is singularly handsome even when out of flower with its graceful curved foliage. It flowers with us in January, and lasts in perfection four or five weeks, being in the house the whole time. The flowers are about 8 inches long, and carry from four to eight blooms each; colour pure white, with a blotch of yellow in the centre of the lip. This we grow in peat and charcoal. Last year they were surfaced with living sphagnum, which improved their appearance materially, and the plants are this year flowering better than usual. Whether this sphagnum is accountable for the improvement or not I cannot say. This species is well supplied with water all the year round.—HANDY ANDY.

VANDA AMESIANA.

This pretty species is proving a very valuable addition to our winter flowering Orchids. It has been in great beauty for the last seven weeks in the collection belonging to Edward Ellis, Esq., Manor House, Wallington. There is half a dozen fair sized plants, four of which are carrying two spikes each, the others having three spikes. One of these has sixteen leaves, and branching spikes, with more than a hundred buds and blooms, the total being 230 blooms. They have been grown by Mr. T. A. Glover, the gardener, in the East Indian house, but he has them now very tastefully arranged in the Cattleya house along with *Oncidium varicosum*,

O. tigrinum, *Calanthes*, *Saccolabium giganteum*, *Odontoglossum Oerstedii* in a pan with three dozen blooms, *Cypripedium Sedeni*, *C. Maulci*, *Dendrobium Ainsworthii* roseum, *Laelia autumnalis*, besides others, and dwarf plants of *Poinsettias*, &c.

ANGRECEUM SANDERIANUM.

A STRONG plant of the above commenced in June, 1888, to throw a spike which is now 3 feet long and continues to grow, but there is no more sign of it flowering than there was six months ago. The plant has not suffered in the least, and there is now another spike 18 inches in length and double the thickness of the oldest one. The latter has progressed very slowly since the other started.

LYCASTE PLANA.

In the same garden are some well bloomed examples of the above, the largest has thirty expanded blooms. There appears to be as much variety in this species as there is in *L. Skiuneri*, for the flowers on the various plants are in no instance exactly alike, some having much darker sepals than others, and the markings on the petals and lip vary considerably. I have sent a bloom each from three plants for your inspection.—G. W. C.

[The varieties of which flowers were sent were well marked, and one in particular was very distinct, the sepals being unusually dark.]

VANDA KIMBALLIANA.

ONE of the smaller growing and small flowered Vandas, that named above, is yet well worthy of notice and a place in Orchid

FIG. 6.—VANDA KIMBALLIANA.

collections. The flowers are about the size shown in the illustration (fig. 6), and their chief beauty consists in the contrast between the pure white sepals and petals and purplish violet lip. They are freely produced, and as they stand well should prove useful for cutting; they would be charming for buttonholes. Messrs. Low & Co., Clapton, were awarded a certificate for this Vanda at the Royal Horticultural Society's meeting on August 13th, 1889.

NOTES ON EARLY ENGLISH HORTICULTURE.

(Continued from page 441 last vol.)

I HAVE already referred to the influence exercised in England by two great gardeners of France—viz., Le Notre and Quintinye, one of these distinguishing himself in ornamental, the other in useful gardening. Of Le Notre, indeed, it has been asserted that he may bear the title of the prince of gardeners, so much excitement being caused throughout Europe by the new style he introduced, and certainly there never was any gardener who led men to as enormous an expenditure. The outlay upon Versailles alone is reputed to have been considerably over a million of our money, and he laid out many magnificent seats beside in France and elsewhere. Quintinye's less showy work was done in a different way. His book on the management of fruit and vegetable gardens, which passed through so many French editions, was much read in England. Its translators were Evelyn, also later London and Wise. He had frequent intercourse with English gardeners, but refused to settle in this country though invited. At Cashiobury, the seat of the Earl of Essex, one of the noble patrons of horticulture in the seventeenth century, Le Notre was employed to lay out the park, and trees, presumed to have been planted by him, are yet to be seen. Cashiobury was distinguished in addition by its flower garden, said to have been one of the earliest arranged after the

Chinese style. Moses Cooke was head of the establishment in Evelyn's time, and he refers to Cooke as a man well acquainted with the art of gardening, and having a knowledge of mathematics. Later we read of him as concerned in the Brompton Park Nursery; according to some he was one of its originators. He did precede London and Wise, but there seems to be some confusion of dates. This is evident that he in 1676 published a small quarto upon the method of "raising and ordering" forest trees, also he wrote for Evelyn a treatise upon the art of making cider. Owing to the constant succession of wars with France during the reign of William III. and Anne there arose a great demand for cider, the wines, of which a supply used to be had from the continent, being almost excluded. Great attention was, therefore, given to the cider-producing Apples, and to other kinds, a variety of them were raised from seed. The original Ribston Pippin is supposed to have been a seedling of 1688, a seedling of a tree which came from Normandy, and it is said to have lingered till 1835, fruiting even in advanced age. Most of our Apples were of French descent; sometimes ships were brought over, many were raised from pips. The first Norfolk Beefing, or Biffin, probably reached us as a fruit, and seedlings were raised thereby. New varieties were obtained from such old English kinds as the Jennetting, which Ray so commends in 1688 for its early ripening. Seemingly it is the same that older writers called Johnnine, because the fruit could be gathered on the festival of St. John. Our gardeners for the above reason planted more Vines, and trained them along trelliswork as well as upon walls. Capt. Foster of Lambeth was a great grower of Grapes in the reign of William III., and there is still a Vine Street there. Lambeth was, indeed, at that period famous as a fruit-yielding suburb. Its Apricots, Pears, and Mulberries are often named, and quantities of Melons were also grown in Lambeth and in the adjacent Vauxhall.

Sir W. Temple, who was a well-known author of his day, and who studied gardening amongst other subjects, making many experiments at East Sheen, and afterwards at Moor Park in Surrey, praises the climate of London for its favourable influences upon most cultivated plants and trees. A radius of about ten miles round the metropolis, says he, is warmed during winter by the "fires and steams" of the town and its inhabitants. What would he have thought now of the heat arising from its millions of population? But unfortunately much of the land that was orchard and garden is built over. Writing two centuries ago, he remarks that foreigners agreed in commending the fruit produced in the south of England generally; still the shortness of our summers was a drawback. Hence he very sensibly advises the choice of such varieties of fruit trees as would ripen soon in Britain. Allusions which he makes to Chinese gardens prove that reports concerning these had already been brought to England by travellers during the seventeenth century, and attempts had been made to imitate them. While admitting the beauty of a regular arrangement in a flower garden, Sir William remarks that a studied irregularity pleases many eyes, especially if it be so managed as to give the effect of a natural confusion or wildness. But the Dutch formality was to be in the ascendant for a time. It was one of his pet notions regarding a garden that there should be a gentle slope from a terrace next the house to some broader extent below, the kitchen garden being formed beyond the flower garden, and flanked by fruit trees.

After needful deduction from the excessive praise given by Evelyn to the nursery at Brompton Park, conveyed in a somewhat ludicrous style, it is still evident that this establishment spreads its influence by degrees over the greater part of this island. If not positively the oldest London nursery, it ranks amongst these, since it appears to have been started nine years before the Revolution. The original extent afforded a good range for horticultural operations, this being about 100 acres. Part of the land had been a park, attached to the mansion once occupied by Henry Cromwell, and a long line of wall was found serviceable for Vines and other fruit trees. Lukar's name is the first mentioned in connection with this nursery. It seems also to have been spelt "Lucre," perhaps by printer's error, and probably its possessor did not think this appellation an improvement. The dates are doubtful, but Cook, already mentioned, became a partner, also London and Field, in or about 1690, the firm consisting then of four persons. Evelyn's observations, however, made in 1694, show that then George London and Henry Wise were the sole proprietors of the place, as he commends them alone for the wonders to be seen at this nursery, "the store and variety, the skilful making, plotting, laying out, and disposing of the ground to the best advantage," and so on. Indeed no other English, nor any foreign nursery, so well exemplified horticultural progress to that date. London had been gardener to Bishop Compton, at Fulham Palace, afterwards he was superintendent of the Royal Gardens—a man, says Switzer, very partial to horse exercise, which is not a common thing amongst gardeners I fancy.

London was, it is likely, the first gardener who had to assess the

damages done to a garden—its trees and shrubs. This he did for Evelyn, after Czar Peter had occupied Sayes Court, and not only neglected but wilfully damaged the grounds, as proved by London's statement of May 9th, 1698, his estimate of the outlay required being £55. He adds, however, that the injury to many of the shrubs was irreparable.

After many vicissitudes, it is curious to note that part of this old demesne of Evelyn's is now converted into a public garden. It was from the establishment of London and Wise that gardeners learnt to use evergreens more extensively in planting, and the firm obtained from abroad varieties of trees suitable for parks and shrubberies previously unknown here, and people came from all parts of Britain to study their improved modes of garden arrangement in all branches.—J. R. S. C.

REIDIA GLAUDESCENS.

THE species comprised in the extremely large and peculiar natural order Euphorbiaceæ are remarkable for their great diversity in habit. The majority are herbaceous plants with simple leaves and insignificant flowers, and are widely distributed through temperate and tropical countries. Some, the inhabitants of dry regions, assume the appearance of Cactaceous plants, with strangely formed succulent leafless branches and stems. Others, chiefly Crotons, are largely cultivated in our hothouses for the beauty of the foliage, and a few species of Euphorbia and the well known Poinsettia are general favourites owing to their brilliantly coloured bracts. The Phyllanthuses and Xylophyllas have flattened leaf-like branches, on the margins of which are produced bright and pretty little flowers, and are well worth cultivating; but for general elegance *Reidia glaucescens* can scarcely be surpassed by any of its numerous strangely varied congeners. This plant was introduced to the Royal Gardens, Kew, from Siam in 1864 by Mr. Thomas Christy, jun.

The genus *Reidia* comprises about a dozen species, chiefly natives of India, but mostly inferior in decorative value to the one under consideration, which, although of such recent introduction, has become a great favourite with cultivators. It owes much of its gracefulness to the slender branches along which the oval leaves are arranged in a two-ranked (distichous) manner, each branch greatly resembling a pinnate leaf. From the axils of the true leaves hang the flowers on filamentous peduncles, and to a casual observer the flowers appear to spring from beneath the branches. The flowers are small and uni-sexual, those at the lower portion of the branches being staminate, with four deeply fimbriated sepals, and those on the upper part pistillate, with six similar sepals and longer peduncles. The sepals in both forms are of a greenish tinge towards the margin, crimson in the centre and on the under surface, the peduncles also being tinged with red.

The plant is of easy cultivation, as it only requires a light open compost of loam, sand, and peat or leaf soil, with good drainage, and a brisk moist stove temperature. Under such liberal treatment it thrives rapidly, and as the small but pretty flowers remain on the plant for a considerable time during summer and autumn it amply repays for cultivation; in fact, even when its flowers have fallen, the graceful habit of the plant renders it very attractive and distinct for associating with other plants in groups.—L.

FORCING RHUBARB.

UNLESS roots of the earliest Rhubarb are grown for forcing there is sometimes difficulty in maintaining a supply during the early months of the winter, for whatever convenience there may be they are known in some cases to absolutely refuse to grow for several weeks, causing much inconvenience and anxiety. With those who have some of the early varieties this difficulty is perhaps unknown, and since this question of variety was so fully brought forward last year by several correspondents of the *Journal* growers are encouraged to act on the suggestions, and secure new stocks either by roots or seeds.

On the season no doubt depends the issue of easy forcing or the contrary, for, like most deciduous plants, frost hastens the maturity and rest apparently required previous to the excitement into renewed growth. That this is true is proved by the fact of many exposing the roots to frost after lifting before they are taken indoors, and to the absence of frost may be attributed the slowness of the earliest responding to the warmer conditions provided for an early supply this winter. My own experience does not stand alone in this matter, for I learn from other gardening friends that the same difficulty has presented itself. Mr. Hilton considers a foot or 18 inches sufficient depth of manure for maintaining gentle heat, but this would depend on the size of the bed and its position, for if exposed to cold winds and snow a narrow bed of that depth would

quickly lose its heat, not be easily restored without further additions being made.

The best system of outdoor forcing I have seen was to have the Rhubarb planted in beds two rows in each, and between them was a trench 18 inches deep and 2 feet wide; this filled with sweetened manure acted at once on the roots, and never failed to excite an early growth. The pots are placed over the crowns in the ordinary way, and only partially covered with litter. The open trench, which may be cleared of the manure at any time before autumn, would act favourably on the early ripening of the growth, and prepare it for an early start, as a large surface is in this way open to the action of the frost, as well as that of the sun and wind.—W. S.

MANNERS AND CUSTOMS—A CATALOGUE COMMENTARY.

(Continued from page 15.)

Lady Mary Fitzwilliam (Bennett, 1882).—This is a Hybrid Tea Rose, which makes very short growth. We can hardly call it weak, because that generally implies some debility of constitution and want of free-flowering qualities, whereas this Rose is of hardy, lasting, and strong, though quite dwarf habit, and very free flowering, which weak Roses are not. A capital sort. It is surprising what a number of good and quite large blooms a very small plant will produce. Not liable to mildew, but apt to be gummed by rain. The blooms come well, of excellent shape, and fair lasting qualities, the petals being large and fine. A good autumnal Rose, and one of high merit in many ways. Changeable in colour, often coming nearly white.

Lady Sheffield (Postans, 1881).—A pretty good show Rose, of rather poor growth, distinct colour, good shape, and fine stout smooth petals, but with no further peculiarities.

La France (Guillot, 1867).—This is a Rose by itself, of great merit, and of a thoroughly distinct type, supposed to be a Hybrid Tea. Two followers have lately appeared—Duchess of Leeds, a seedling; and Duchess of Albany, a sport—both very similar to it in general appearance. The growth and foliage are good and very characteristic, partaking much more of the Tea habit than such acknowledged hybrids as Her Majesty and Mary Fitzwilliam. Not very liable to mildew, but rather sensitive to rain. The blooms come generally well, but sometimes the strongest are too spherical and ball like, losing their points. Petals good, but centre rather weak; beautiful colour, but rather difficult to keep "clean." It should have a striking silvery brilliance. In freedom of bloom, and as an autumnal, of the very highest class; of the largest size, but a bad laster, and must be cut small in hot weather, as it opens quickly. Has a most distinct and exquisite scent. Merit on this point would be difficult to settle, as tastes differ so much. I saw lately somewhere a selection of six Roses as the sweetest scented, and they all had the Tea scent, which to me is not pleasing. I should place the Rose under notice at the head of the list. It would occupy the same proud position in the estimation of a good many as a general all-round Rose for everybody, for it is hardy and of strong constitution, and will do well, or even better, on rather light soil.

Le Havre (Eude, 1871).—Of fair but not strong growth, with good foliage; not specially liable to mildew, but rain will impair its good qualities. A beautiful show Rose, one of the very best examples of the imbricated form, but the blooms will not come of good shape or colour in bad weather. Like Fisher Holmes and some others, this Rose shuts up at night, the outer petals crinkling inwards; not free in bloom or a good autumnal, but with a very high reputation for its lasting qualities.

Lord Macaulay (W. Paul, 1863).—Of fair growth and foliage, presenting no striking peculiarities. Of good bright colour, and very full shape, but medium in size, and not first class in free flowering or autumnal qualities.

Louis Van Houtte (Lacharme, 1869).—Of weak growth and small foliage; not much liable to mildew, but is injured by rain, and will burn in a hot sun. The blooms will only come fine if strong shoots are produced; and this is a difficult task with purchased plants, as the constitution is weak and does not bear removal well. It is best to bud it annually; but plants which have never been moved will sometimes do well as cutbacks for a few seasons. Not free blooming or good as an autumnal, requiring high culture, but a grand bloom when you get it good, with stout petals, full centre, rich colour, fine globular shape, and full size. The lasting powers of the blooms are particularly good, and it is worthy of notice as an example of the old manners and customs of Roses, that many of the weakest growers have the most lasting flowers, and *vice versa*. For instance, Marquise de Mortemart and Madame Ducher are, I should think, about the worst growers among H.P.'s that we have, and these two Roses are especially noted for the lasting qualities of their blooms, while the strong growers, Dupuy Jamain and Thomas Mills, show the opposite side of the picture.

Mabel Morrison (Broughton, 1878).—A pure white sport from Baroness Rothschild, but smaller, and very weak in the centre; is only worthy of notice as a seed parent of Her Majesty.

Madame Charles Wood (Verdier, 1861).—Of robust but weak growth; does not like being moved, and will not do well in some places. In fact, it does so badly with me that I am afraid I shall have to discard it. The blooms often come divided, and rain will spoil them. Yet sometimes a strong fine Rose, with large petals, well filled in the centre, and incurved in a characteristic manner. Not a free bloomer or good autumnal, but a good lasting flower, of full size.

Madame Clemence Joigneaux (Liabaud, 1861).—A very strong grower, with fine coarse foliage, not liable to mildew or to be injured by rain. The blooms are apt to be rough and badly shaped, and it seldom has sufficient form or smoothness for exhibition. Of large size and very sweet scented, but rather a dull colour. A free bloomer, but not particularly good as an autumnal. A hardy useful Rose for cottage gardens, a strong constitution, and will do pretty well in light soil.

Madame Crapet (Fontaine, 1859).—An old Rose, but still hard to beat at its best, as a smooth refined show Rose of the popular imbricated shape. Rather a weak grower, and liable to mildew, but can stand some rain, and well repays high cultivation. This Rose, like a good many others, has its good and bad years, and was particularly good with me last season. Capital imbricated form, very smooth and full, of good lasting quality and fair size. Not a free bloomer or good autumnal, but, though never of strong or hardy constitution, cannot be suspected, like some others of its age, of having undergone any deterioration.

Madame Ducher (Levet, 1879).—This is perhaps the worst grower of all H.P.s. It is impossible to do anything with it except by annual budding on strong stocks, and even then it will not grow many inches. This being the case, it is of course only grown for show purposes, and a lovely bloom may sometimes be obtained, large, bright, and smooth, of perfect shape, and (as mentioned before) wonderfully lasting. It will "stand" and maintain its lovely form in a hot tent as firm as if carved in wood.

Madame Eugène Verdier (Verdier, 1878).—Grows well as a maiden, though spring growths of cutbacks are sometimes very short; but the blooms come quite as well, and the foliage is fine. Not very liable to mildew, but much rain will cause the petals to "gum" (stick together), and a slight shower will stain the colour. The blooms are likely to be coarse, and are not often of refined shape or appearance; but they are very large, with wonderfully fine petals, and well-filled centres. Fairly free in bloom, and a pretty good autumnal; the shape is globular, but delicacy and regularity of outline are often wanting. I showed one last season that was very much like a prize Cabbage in shape and (I was almost going to say) size, for this is quite one of the largest Roses.

Madame Gabriel Luizet (Liabaud, 1877).—A Rose of distinct manners, of strong vigorous growth, after the manner of a summer Rose. The foliage is good, and maintained throughout the autumn more completely than any other H.P., but is very liable to mildew. The blooms are occasionally divided, but generally good. On cutbacks they all come at once (also after the fashion of summer Roses), and as they will gum and rot with wet, two or three hours of rain at a critical time will destroy three-quarters of one's crop. It is not good as a laster and below the average in size, but has fair petals and centre, with a capital point, and is noted for its colour, which is perhaps the most attractive shade of pink we have. A very free bloomer in the season, but one of the worst autumnals we have, with me. Others say they find it quite good in this respect, but I should say that I do not get on an average more than one autumnal bloom to each large plant. Hardy, and of strong constitution, very thorny and free in growth, forming quite a big bush in good soil.

Madame Hippolyte Jamain (Jamain, 1871).—Of good smooth growth and foliage, not very liable to mildew, but injured by rain. A coarse Rose, generally rough and irregular if grown strong, but sometimes of even globular shape, and then valuable for exhibition, as it is very large, full, and lasting. Not of much use as a free bloomer or autumnal. It should be noticed that there is a good Tea Rose of exactly the same name as this, besides Hippolyte Jamain H.P.

Madame Isaac Pereire (Margottin, 1880) seems to be a Perpetual Hybrid Bourbon, of strong good hardy growth, with fine foliage. I have not tried this Rose very long, but it has not been affected with mildew, and the blooms have come fairly well, not of very refined shape, but of extra large size. It is free flowering, and is well endowed with the two special good points of the Bourbon Rose, being very sweet scented and a thoroughly good autumnal.—W. R. RAILLEM.

(To be continued.)

ON IMPROVING ROSES.

It is not an uncommon occurrence for Roses to grow grossly and produce comparatively few blooms, and these only of poor quality, while some are found to make poor growth with few or no flowers, and in both cases the cause of the mischief may arise from insufficient root action; in the first case noted the roots being gross, and the rootlets almost wholly absent, and in the second instance few roots of any kind being produced at all. Though not a rule without the proverbial exception, it is a fact that many rootlets produce a growth short jointed stiff, hard, and free to flower. Once secure such a condition under ground,

and the rest is pretty sure to follow. Food may be given with benefit, the knife being employed with certainty either in pruning or in thinning out extra growths, and plenty of good blooms arrive in due time. But with gross-growing Roses, how is this condition to be brought about? I have seen transplanting, or rather, to speak more correctly, lifting and replanting tried, but with very bad results. And no wonder; the plants to be operated on have a strong, unripened growth, drawing, doubtless, a very inferior class of food through their corpulent root members. But, still, it is a food. Up come the plants root and branch, and our watery fed friends very soon find themselves absolutely starved, for the roots are of a class which do not quickly adapt themselves to changed circumstances, and the final result may be shortly stated as a lot of cut-back stumps, with a few weakly growths which have no power to react on the poor roots, and the Roses are lost and transplanting condemned. Something of the same kind happens with the weakly plant, though in this case the reason would be for want of roots to make anything of. Transplanting Roses to be beneficial must be a settled method of culture, so that the roots may be found in numbers radiating from the rootstock, and if a condition of grossness appear then the check the plant receives will be of a short-lived nature, not so lengthened as to stop supplies, as many of the roots will resume activity at once, but in a less lively form, and the result in spring will be a sturdier, firmer growth, perhaps not much less strong than in the previous season, but certainly more consolidated and productive of better bloom.

What, then, ought to be done with bushes which have been left for years in the same place, and which have become so unsatisfactory as to call for prompt measures to secure a free-flowering habit? I should say let the plants remain, but cut the roots; and here it is necessary to explain that unless "cutting the roots" is undertaken in a judicious manner the results may be as disastrous as lifting and replanting would have been. If the plants have been from three to five years in the same spot, then in most cases it would be perfectly safe to dig narrow trenches round the plants, cutting every root in the process, and that with the best results; but should the plants have been left for many years, and increasing in grossness, then such a drastic measure would defeat the purpose in view, and most probably death would be the result. In this case the common sense method would be to inspect the domestic arrangements with caution, and by cutting clean off from the culinary department the one half of the roots the plant itself would be kept in health until those so cut had formed a foraging company, when the improved class of food would be apparent the first season; then the following year complete the process by cutting off the half left the previous season, and it would not be amiss perhaps to take a look at the half cut at that time, and if any young roots should be found exhibiting a disposition to ramble they also may be cut. In order to secure the very best results from the above treatment a good dressing of loam or other good material should be applied close to the cut portion, or if plenty of fresh soil can be had then fill up the trench entirely with the new, raising any of the smaller roots, and laying them in this; but even where there is no soil to add, the mere cutting of the roots and turning over and breaking up the soil will be found of very great benefit. If dung is to be used let it be placed as a mulching above the roots, and that portion where the young roots may be expected to make growth. In the case of very thick-rooted plants it will be advisable to prune to a good plump bud for the first year. Afterwards all ugly growths may be cut level with the ground to the advantage of the plants. It may be remarked that own-root Roses are more apt to require root-pruning than those budded on the Manetti, and it is equally to be noted that these remarks do not apply to any other garden Rose, which need not on that account be altogether neglected.—B.

HARDY ROSES.

THE late severe frosts have been a fair test of the hardiness of some sorts of Roses over others. It has never been in my power to cut fair blooms from standards unprotected in the month of January before. Out of about fifty varieties on the 5th I cut Général Jacqueminot (quite bright), M. Annie Wood, Gloire de Dijon, Souvenir de la Malmaison, Alba Rosea, and a dark crimson which I am unable to name. This I have submitted to many judges at shows and to Rose growers (Smith's of Worcester among others), with the result of seldom, if ever, getting two alike in deciding its name. The name I had with it was "Prince Imperial," but I find no such name in catalogues. Out of about half a dozen dark Roses this I consider my best. In summer it is much darker, and of a rich velvety shade. I should be glad of any information respecting it.—J. HAM.

FRAGRANT ROSES.

SOIL has an influence even on the fragrance or otherwise of Roses, but climate seems to exert the greatest influence on perfume. When the atmosphere is dry flowers have little or no fragrance. A Rose which at midday would be pronounced scentless, is in the evening, or in the morning when the dew is on it, extremely fragrant. Moisture seems essential to a fulness of perfume. Blooms set up in damp moss are more fragrant than others in water in cups on a bare green stand or a baize covered table. A bed or border of a dozen or any number of varieties will have perfume in proportion to the per-centage of varieties having that characteristic. It is vain expecting perfume in Roses that are selected indiscriminately, trusting to the sentiment of enthusiasts, who, planting Roses, expect the air to be for ever afterwards laden with perfume. Those planting a select hundred may find that the very thing they require is lacking, and for cutting purposes there is no question of

a fragrant Rose being most esteemed. Some who understand Roses for something more than exhibitions, and for display in gardens, plant largely of the ignored Cabbage Rose, and other old and esteemed favourites, for the sole purpose of cutting. They go further, and plant by the dozen or hundred those that have the desired characteristics of beauty with floriferousness and scent. These are, or should be, termed garden Roses—showy and sweet. To adhere strictly to that would, however, exclude some of the very best for decorative purposes. Those that require scented Roses must plant them, and some of those that are good alike as garden and drawing room are the following:—

Of Hybrid Perpetuals few have the brilliancy of Alfred Colomb, carmine crimson, which may not be always as full scented as desired, yet it is a fine masser, very showy. Charles Lefebvre in mass is a dazzling crimson scarlet, rich and velvety, and mostly fragrant. Earl of Dufferin is an early, continuous, and late bloomer, brilliant velvety crimson, and full scented. Harrison Weir, velvety crimson, enlivened with scarlet, and full scented even in autumn. Lady Helen Stewart, crimson scarlet, commencing with the earliest and continuing with the latest, an exceedingly fine Rose, and highly perfumed. Mrs. John Laing, light pink, very profuse, continuous and late bloomer. Mrs. Jowitt, crimson shaded lake, generally, but not always, very fragrant. Marchioness of Exeter, rose, flushed cherry red. Madame Ferdinand Jamin (American Beauty), rosy carmine, as good as sweet. La France, satiny pink with rosy centre, is mostly sweet. R. C. Sutton, deep rose, reverse of petals white, very free, and one of the sweetest Roses extant. Countess of Pembroke, satiny rose, usually fragrant. Sir Rowland Hill, ruby claret, shaded maroon. Duchess of Albany, deep pink, of the La France type, are novelties of great merit, and very sweetly scented. Those are all good growers, making effective beds or groups as dwarfs, either worked or on own roots. Others that may be noted as generally good and sweet are Beauty of Waltham, cherry crimson, hardy and free; Abel Grand, silvery rose, early and free; Senateur Vaisse, crimson, an old favourite; The Puritan, pale yellow, changing to white; Madame Gabriel Luizet, satiny rose; Mr. James Brownlow, bright carmine. The last, with Marchioness of Lorne, are new; the last is rose shaded carmine, both promising to be good garden Roses. Caroline d'Arden is also new, soft rose, and a very profuse bloomer. Beauty of Beeston is a dwarf Charles Lefebvre, and more open, having the same brilliant velvety crimson colour, and is in strong contrast to Bessie Johnson, blush-white. Catherine Bell, rose, free flowering and of very free growth, almost, if not quite, climbing, which class cannot endure hard pruning, being best treated as pillar Roses. Madame Désir, salmon rose, rather small; Madame Wilson, rose, free flowering; Madame Montel, delicate rose; Heinrich Schulteis, rose pink; Miss Hassard, pinkish flesh; and Miss Poole, silvery rose, shall close my list of Hybrid Perpetual Roses with scent, with Madame Eugène Appert, rosy pink.

As Hybrid Perpetuals are everybody's Roses from their being perfectly hardy, we may mention others of the same class, which, if not scented, are nevertheless first-class for buttonholes—viz., Emperor, very dark, i.e., black; Empress, white, pink centre; and Brilliant, scarlet crimson. Roses that are worth growing in quantity are Charles Lamb, bright red; Anna Alexieff, rose pink; Glory of Waltham, crimson; Brightness of Cheshunt, vivid brick red; Charles Dickens, rose; and Garden Favourite, pink. Ella Gordon, bright cherry; and Gloire Lyonnaise, chrome yellow, edged silver-white (and fragrant into the bargain), are both large.

To return to odoriferous Roses we may mention the somewhat uncommon crimson Perpetual, or Rose du Roi; Damask, light crimson, very fragrant; and of the Perpetual Moss Souper et Notting Rose is sweet. Of this class Mrs. W. Paul is one of the best, and Perpetual White Moss indispensable, though Blanche Moreau, pure white, is superb. Those all require close pruning and liberal treatment. Of the Ile de Bourbons the only one of note for scent is Queen of the Bourbons, fawn.

Of the Tea-scented, which, however, are not hardy, but are best grown outdoors against walls with south or south-west aspects, Comtesse de Nadaillac, coppery orange, salmon centre; Madame Etienne, rosy, changing to pale rose; Dulse Bella, coppery rose; Viscountess Folkestone, cream pink, salmon centre; Nancy Lee, satin rose; Michael Saunders, bronzy pink; and Viscountess Falmouth, pinkish rose, for low walls, adding W. F. Bennett for affording the finest of all red buds for cutting. The last five are Hybrid Teas, and to those may be added The Puritan, already named in the Hybrid Perpetuals. For high walls or buildings Maréchal Niel must head the list. To see this Rose at all perfect it requires to be grown under glass, but there is no dispute about Waltham Climber No. 2, red, and one of the sweetest Roses in existence; and of Noisette Céline Forestier, rich yellow; and Jaune Desprez. No Rose whatever is so satisfactory against a wall as Gloire de Dijon. Some say it is sweet, and others fail to be struck by its fragrance. Then there is the Banksian Fortuniana, white, white and yellow, cream and yellow, which is passed by Jaune Sérin, bright yellow. These require a south wall, and flower early. They require long pruning, as in fact do all the climbing Roses, particularly Musk, which have the flowers produced in large clusters late in summer, and when the atmosphere is moist are most distinguished by their musk-like fragrance. A wall with a south or south-west aspect is necessary. Berherifolia Hardi has single flowers, yellow, with maroon spots, and is of dwarf habit. Fringed, pink, semi-double, Princesse de Nassau, cream, changing to white, and Rivers' Musk, creamy white, and of moderate growth.

For covering wirework in the open, Ruga, flesh; and Splendens,

white tinted flesh, are the sweetest of the Ayrshire Roses, and none other by scent in climbing Roses have attracted.—UTILITARIAN.

CANKER IN FRUIT TREES.

I OWE some apologies of long standing to Mr. A. Young and others who favoured me with specimens of Apple tree wood some time ago for inspection, and a request to reply to through the Journal. I did not consider Mr. Young's specimens were canker wounds, but in two cases out of three there appeared to have been bits of bark taken off by some animal, probably a rabbit.

Another case was a piece of Apple tree wood, the centre of which was eaten away by a grub. This was quite a new enemy to me I am pleased to say, and was in no way connected with canker.

While on the subject I beg to acknowledge the pleasure it gave me to read "W.'s" last references to this subject, and also how much I enjoyed in fancy the rambles from one lovely spot to another in our county, all of which I have had the pleasure of visiting within the past few years. When Mr. Tonks held me up to readers as a model of ignorance by not knowing thrips I did not think it worth while to reply, but I may now state that thrips are, unfortunately, as familiar to me as earwigs or woodlice, and about as likely to be mistaken by me. It would be quite as near the truth to say I could not tell his little fat roasters (which we put out of his garden) from ferrets, a greyhound from a mastiff, or a jackdaw from a swallow.—J. HAM.

EVENTS OF THE WEEK.—The Royal Society has a meeting at Burlington House to-day (Thursday) at 4.30 P.M., and the Linnean Society at 8 P.M. Messrs. Protheroe & Morris have a sale of Orchids at their Cheapside Rooms on Friday, January 17th. The Royal Geographical Society meets on Monday, January 20th, at 8.30 P.M., and the Society of Arts on Wednesday, at 8 P.M.

— AT a general meeting of the ROYAL HORTICULTURAL SOCIETY, held January 14th, Mr. James Douglas in the chair, the following ladies and gentlemen were elected Fellows of the Society—viz., Viscountess Wolseley, Rev. A. B. Alexander, C. Pennell, J. E. Brown (Australia), T. R. Butler, D. Campbell Brown, T. H. E. Compton, J. Cooper, De B. Crawshay, Mrs. Morland Crofield, Mrs. Curwood, A. Dean, S. H. Dean, J. T. Diamond, J. T. Gabriel, Rev. Geo. E. Gardiner, F. T. Good, Mrs. Grinling, Mrs. Grove, E. A. Hambro', J. Henderson, W. H. Hudson, C. Jeffries, J. W. Justen, H. H. Kneeling, H. J. Kershaw, John Laing, W. B. Latham, T. Laxton, Miss Agnes Mellish, Arnold Moss, R. R. B. Orlebar, W. Owen, Rev. F. Page Roberts, W. W. Palmer, F. A. Philbrick, Q.C., F. W. Prior, Hugh Pye (Australia), J. Rawlins, W. M. Rose, Miss Rotch, Geo. Steel, A. J. Veitch, J. C. Wakefield, H. Wallis, A. C. Wheeler; as Associate, John Slack.

— THE weather in the south of England still continues most variable, rain and cold winds alternating with bright warm days. Sunday, January 12th, was quite exceptional, however, the sun shining brilliantly from an unclouded sky the whole day, followed by a clear starlight night, but no frost. A daily paper says, "Seldom at so early a period of the year have the parks presented so animated a spectacle as they did yesterday. Hyde Park and Kensington Gardens were crowded, as well they might be, considering the spring-like balminess of the atmosphere and the delightful sunshine. Sitting out in the open air was, during some portions of the day, quite a pleasant and almost a safe thing to attempt, and cumbersome greatcoats were very generally discarded. Parks have become not merely agreeable luxuries but absolute necessities to city life, and the local administrator who economises in this item of expenditure does so at the cost of the health and happiness of the people." Monday was damp, dull, and cold, but two such days as that preceding it could not be expected together at this time of year.

— THE WEATHER IN THE NORTH.—The days have, with almost regular alternation, for some time been fine and wet. Very high winds with pelting rain have occurred on many nights lately. Only twice for the last fourteen days had the thermometer fallen to freezing point, 6° of frost being registered for a short time on the night of the 2nd inst.—B. D.

— AT a Committee meeting of the UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY, held at the Caledonian Hotel on Monday last, Mr. R. Scott in the chair, five new members were proposed from Cardiff, Halifax, Battic, Sussex, Rochampton, and County Cork. Messrs. A. J. Green and Geo. Dixon were appointed Auditors, and it was unanimously resolved to ask Mr. J. Wright to take the chair at the annual general meeting, which will be held at the same hotel on February 10th at 8 P.M.

— PREVENTION BETTER THAN CURE.—Now the influenza is so prevalent the following note may be of interest. All the greatest authorities advise the taking of quinine twice a day as a precautionary measure. As this epidemic is spreading so rapidly in all directions Messrs. Sutton & Sons of Reading lost no time in adopting this suggestion. They at once ordered between 500 and 600 doses of quinine to be delivered daily for gratuitous distribution amongst their large number of employés. This action has been gratefully appreciated by their hands, and has had a most successful result.

— THE FOLLOWING BULBS, PLANTS, AND SHRUBS ARE NOW IN FLOWER OUT OF DOORS AT BLACKROCK, CORK:—*Narcissus pallidus praecox*, *Tazettas Seilly* and *Paper White*; *Snowdrops*, all sorts; *Hepaticas*, double red; *Triteleia uniflora*; *Lenten* and *Christmas Roses* in endless variety, particularly the *Lenten Roses* from Mr. Archer Hind's collection. There are all sorts of *Primroses*, double and single, *Aubrietia graeca*, *Gentiana acaulis*, *Violas* of sorts, *Iris stylosa*, *Schizostylis coccinea*, *Emperor Stocks*, and *Wallflowers*. The beautiful *Prunus Pissardi* is becoming full of buds, *Mahonias* are in flower, *Pyrus Maulei* and *Azara microphylla* are crowded with bloom. The *Daffodils* are very promising. We shall be having 100,000 blooms of *Ard-Righ* in one month from date all in the open air.—WM. BAYLOR HARTLAND.

— ROYAL BOTANIC SOCIETY OF LONDON.—A meeting of this Society was held on Saturday, January 11th, Dr. R. C. A. Prior, F.L.S., in the chair. Among the donations presented to the museum was a specimen of the Double Cocoa Nut or *Coco de Mer*, now known to come from the Seychelles, a small group of islands in the tropics. For some hundreds of years these nuts have been occasionally found washed up by the sea, where their extraordinary appearance, large size, and mysterious origin gave rise to many stories of miraculous virtues in the cure of diseases, some are even said to have been sold for their weight in gold. This specimen had belonged to General Gordon, and was given by him to General Gerald Graham, by whom it was presented to the Society.

— FLORAL DECORATIONS AT THE COUNCIL HOUSE, BIRMINGHAM.—The present Mayor of the city, Mr. Councillor Clayton, gave two balls on an extensive scale recently, one on the Wednesday, Jan. 8th, for his friends, the next on the following evening, a fancy ball for children. Mr. W. Spinks, Manager of Messrs. Hewitt's nurseries, supplied all the floral decorations, and certainly the finest display ever seen in Birmingham, and that is saying a great deal. Artistic arrangements, and an unlimited supply of specimen Palms, and a host of *Poinsettias*, *Euphorbias*, *Richardias*, *Hyacinths*, *Tulips*, *Lily of the Valley*, and so many other plants were everywhere, and the Council House is a very extensive place, well suited to floral decorations. A splendid ice cavern was fitted up, occupying a spacious room, and under the electric light was an object of especial admiration. In the reception room, fitted up with oriental splendour, a group of *Orchids* and *Adiantum farleyense* was a prominent feature, as well as two groups of *Calanthe Veitchi* and *Ferns*. A large basket of *Narcissus* blooms was presented by Mr. Spinks to the Mayoress.

— SUTTONS' TRIUMPH MELON.—Now that this Melon is for the first time placed in the hands of the public I thought a little of its history might not be out of place in the Journal. It is the result of a cross between *Scarlet Premier* and *Eastnor Castle Green-flesh*, and is of superior flavour. I have found it a free setter, and to succeed well in frames with little or no artificial heat. It obtained a first-class certificate at the Crystal Palace, and the first prize at the Chiswick Summer Show two years in succession, and various other prizes. I have found it excellent for pot culture, but my practice has been chiefly to grow the plants on the restricted system in frames—viz., three plants to a light, and from two to three fruits on each plant. For the last two seasons, however, I have been unfortunate enough to be troubled with a bad case of clubbing in the Melons, so that the variety has not really had a good and fair trial with me. With others I hope the good qualities of this Melon will be developed.—W. PALMER, *Thames Ditton*.

— GARDENING APPOINTMENT.—We are glad to learn that Mr. James Udale, lately of Elford Hall Gardens, Tamworth, has been appointed gardener to Lord de Ramsey, Haverland Hall, Norwich.

— WE are informed that MESSRS. BARR & SON have removed from Tooting to Long Ditton, and the nursery at Tooting has ceased to exist. Narcissi and other specialities of Mr. Barr will be cultivated on an extensive scale in the new establishment.

— A CORRESPONDENT desires information on the manufacture of SUGAR FROM BEET, also on the preparation of condensed milk, and will be obliged if any of our readers can recommend any published work on those subjects in English, French, or German.

— THE DUTCH HORTICULTURAL SOCIETY.—The dates for the meetings of Committees of the above Society in Amsterdam during 1890 are as follows:—12th February, 18th March, 15th April, 14th May, 19th June, 17th July, 26th August, 25th September, and 12th November.

— A MELBOURNE correspondent informs us that they are having "a very fine season, plenty of rain, heavy crops, and abundance of fruit. In all my thirty-six years' experience I never saw better prospects for both agricultural and horticultural interests, and this applies to the whole of Australia."

— THE annual dinner of the WIMBLEDON AND DISTRICT ROYAL HORTICULTURAL SOCIETY will take place on Monday, January 20th, at 6.30 P.M., in the Dog and Fox Hotel, Wimbledon Hill. This Society is advancing rapidly in importance amongst those in the suburbs of London, and a large gathering is expected. Dr. Walker and Mr. G. Lyne are the Hon. Secretaries.

— THE BIRMINGHAM CHRYSANTHEMUM SOCIETY.—We have to record a very successful financial result of the Society's Exhibition in November last, the total income of the Society for the year being £500, and the expenditure £420, having a balance in hand on the year of £80, and a reserve fund of £277. It is very probable, we hear, that the large prizes will again be offered next November for forty-eight blooms.

— THE annual dinner to the heads of departments in the King's Norton Nurseries, as well as the branches of the business of MESSRS. POPE & SONS, BIRMINGHAM, was given by Mr. John Pope, at his residence, last week, when several gardening friends were invited, and a toast to the health of Mr. and Mrs. Pope, and Mr. Pope, senior, was given by Mr. Brown, of Elmdon Hall Gardens, and met with cordial reception.

— THE BLACK MAZZARD CHERRY.—I was somewhat interested in the article on the Black Mazzard Cherry tree at page 16. We have here some wild Cherry trees, which were found in a wood. The fruit is small, light red, very sweet and fleshy, having a smaller stone in proportion to its size than the Mayduke, and it ripens about the same time as the Morello. It is a free grower and an abundant bearer, and I am of opinion would be a capital variety to bud or graft other varieties upon, while its free growth renders it ornamental as a deciduous tree.

— THE WEATHER is, and has been, mild for the season. Flowers have never been absent from the borders all winter, and one of our seedling Snowdrops was in full bloom on the 8th of January, being much earlier than any other variety.—W. T., *Blantyre*.

— THE WEATHER IN DECEMBER.—The weather during December was very variable, sharp frosts and spells of mild weather alternating in rapid succession. On the whole very dull, there being only seven bright days. Rain fell on seventeen days. Total fall for the month 1.66 inch, of which 0.50 fell on the 21st. Highest shade temperature 53° on the 17th, 18th, and 22nd; lowest 17° on the 29th; lowest on grass 14° on the 29th. Number of days at or below 32°, in shade twenty-two, on grass twenty-five. Barometer variable, highest reading 30.80 at 9 P.M. on the 5th, lowest 29.32 at noon on the 10th. Garden spring running 18 gallons per minute on the 31st.—J. TUNNINGTON, *Ketton Hall Gardens, Stamford*.

— I AM herewith sending a brief report of the results that have been achieved by the LEEDS PAXTON SOCIETY CHRYSANTHEMUM COMMITTEE, which commenced operations only seven weeks before the Show was held, and without a penny to start with, but with the assurance that the other shows had "always been a failure," and the previous one resulted in a deficit of £40. The total receipts amount to £242 4s. 5d., and the expenditure has been £183 3s. 1½d., thus leaving a balance of £59 1s. 3½d. towards the next Show. The £141 5s. 6d. was received in

subscriptions, and £84 15s. for tickets of admission.—THOS. BONSALL, *Secretary*.

— GOOD VEGETABLES.—In reply to "W. F.," I have grown Michaelmas White Broccoli, but do not think it so good as Veitch's Autumn Giant, and it comes into use about the same time, and do not stand the frost as well. I have not tried Suttons' Favourite or Autumn Mammoth Cauliflowers, but their First Crop and King of the Cauliflowers are the best early Cauliflowers I have tried, but if the first two are better I shall certainly try them. Veitch's Perfection Pea is very good in every way, but I consider Prince of Wales better, and about the same height. Duke of Albany is a very large podder, but very few of them with me; the Duchess of Albany is much in the same way as the Duke. Both these and Satisfaction are inferior to Telegraph with me. There are so many sorts that are good, but if there is one sort which is better than others it is better to grow that one only, thanking "W. F." for his selection all the same.—J. L. B.

— BULLFINCHES AND FRUIT BUDS.—I am astonished that people will continue to harp on the old string that the buds pecked out by birds each contain an insect. I could understand it if the birds given to this practice were insectivorous, but they are not; they are vegetarians, living, except in the breeding season, almost exclusively on vegetable food. Why, then, in the name of common sense should there require to be a grub in each bud? Now, as I pointed out years ago in the Journal, the buds taken are blossom buds, and it is the stored up saccharine matter in the bud, the honey secretions of the future flower, which the birds are fond of. I have no doubt the birds noticed by Mr. Murphy on his Chrysanthemums were either cole tits (*Parus ater*) or great tits (*Parus major*). Both are insectivorous. It is hardly likely they would be lesser spotted woodpeckers. These are too rare in Ireland, and besides they frequent tall trees and not shrubs.—F. B.

— THE annual meeting of the members of the ANCIENT SOCIETY OF YORK FLORISTS was held recently in the White Swan, Goodramgate, Mr. G. Lamb presiding. There was a good attendance. Mr. Lazenby (Secretary) read the annual report, which stated that the Committee had again the gratification to announce very satisfactory results of the past year's operations, there being a considerable increase in the number of members, the receipts from this source being augmented by about £22. Despite the increase of the expenditure, there remained a balance at the bankers of over £100. The minor shows had been well sustained and largely patronised by the public. The Chrysanthemum Show was a distinct advance in the quality of specimen plants and cut flowers on any preceding show, more especially the plants. The financial statement showed that the balance from 1888 was £122 18s. Donations and subscriptions amounted to £136 17s. 6d., the receipts at the Chrysanthemum Show £175 7s. 1d., and other receipts to £44 13s. 2d., giving a total of £479 15s. 9d. The chief items in the expenditure were £142 3s. 9d. for the Chrysanthemum Show, £46 6s. for minor shows, £24 4s. to the Gas Company, £20 16s. 8d. to the *York Herald*, £28 10s. for bands, and salaries £20. A balance of £111 14s. 5d. was left in hand. Mr. G. F. Pilmoor moved the adoption of the report, which was seconded by Mr. W. Robinson, and, after some discussion on details, the proposition was agreed to.

SUTTONS' BOUQUET BROCCOLI.

At the end of last May Messrs. Sutton & Sons of Reading sent us a plant of this Broccoli, at once remarkable by its size and productiveness. It completely filled a hamper upwards of 3 feet in circumference. The plant was bearing a central head 9 inches in diameter, with a number of branches from the main stem just above the ground, with close white heads ranging from 4 to 6 inches across. There is not the slightest exaggeration in the character of the plant we inspected, in the illustration which we are permitted to use from the catalogue of the firm. It is a true branching Broccoli, and it will be interesting to hear that it retains its distinctiveness in various soils and districts.

GARDENERS' ORPHAN FUND.

KINDLY give me a little space to record some generous and most successful efforts which have recently been made in aid of our gardening charities. The promoters and conductors of such undertakings deserve our warmest and most sincere thanks, not only for the time and trouble they have devoted to the work, but for the splendid example they have set others to go and do likewise.

At Worksope last month the gardeners of that dual district, headed by our good friends Mr. Henderson of Thoresby (Secretary), and Mr. Gleeson of Clumber, organised a concert, which, being patronised by the

FIG. 7.

SUTTON'S BOUQUET BROCCOLI.

elite of the place, secured as a result a net profit of £56 4s. for the benefit of the Gardeners' Orphan Fund. In accordance with the rules of the Fund the following members of the Committee have elected to become life subscribers:—Mr. Egglestone, Firbeck Hall Gardens, Rotherham; Mr. Gleeson, Clumber Gardens, Worksop; Mr. Horton, Welbeck Gardens, Worksop; Mr. Henderson, Thoresby, Ollerton, Notts; Mr. Jefferson, gardener, Carlton House, Worksop; Mr. Mailender, Hodsock Priory, Worksop; Mr. Sutton, Worksop Manor Gardens, Worksop; and Mr. Woods, Osberton Gardens, Worksop.

At Reigate the Committee of the Reigate and District Chrysanthemum Society (Mr. J. Brown, Great Doods, Reigate, Secretary) decided to hold their Show last autumn for the benefit of the two great gardeners' charities—the Gardeners' Royal Benevolent Institution and the Gardeners' Orphan Fund. Their efforts have been so successful as to secure a net profit of £100, and with grateful thanks I have to acknowledge the receipt of £50 sent in aid of the Gardeners' Orphan Fund. The following members of the Committee have elected to become life subscribers:—Mr. James Brown, gardener to Mrs. Waterlow, Great Doods, Reigate; Mr. Thomas Budgen, gardener to Miss Baker, Holmfels, Reigate; Mr. Alfred Alphonse, gardener to J. Clutton, Esq., South Park, Reigate; Mr. William Hamilton, gardener to Mrs. Grice, Beechwood, Reigate; Mr. James Hoad, gardener to G. Simpson, Esq., Wray Park, Reigate; Mr. Fred. Parfitt, gardener to E. Horne, Esq., Park House, Reigate; Mr. Wm. Peters, gardener to W. Finch, Esq., Danecroft, Reigate; Mr. James, Port, gardener to J. C. Saunders, Esq., Shagbrook, Reigate; Mr. C. J. Salter, gardener to T. B. Heywood, Esq., Woodhatch Lodge, Reigate; and Mr. Robert V. Smith, gardener to A. G. Taylor, Esq., The Margery, Reigate.—A. F. BARRON, *Hon. Sec. Gardeners' Orphan Fund.*

SELECT HARDY PLANTS.

HEPATICA ANGULOSA.

UNDOUBTEDLY the most charming of the Hepaticas. The flowers when well grown are fully twice the size of any other, and the plant is readily managed in most gardens. All are hardy, but they should always be planted in sheltered warm partially shaded nooks to see them to advantage. Another condition which they cannot endure is a smoky atmosphere; they do not die, but they linger on, living examples, as it were, of their own misery, and in winter not a vestige of leaf is apparent. In a deep rich moist sandy loam the Hepaticas are perfectly happy, and they usually carry their foliage throughout the winter. Some of those positions which suit them well are easily obtainable in the majority of gardens—such, for example, as the margin of Rhododendron beds, or in company with dwarf shrubs, like the Andromedas and Azalea mollis. *H. angulosa* is very distinct from the rest of this group in several important characteristics. Some of these are its five-lobed toothed leaves, which in a young state are inclined to be downy, also in its handsome sky-blue flowers and somewhat creeping rootstock, all the forms of triloba having compact erect crowns. I have now a solitary flower of this species which has evidently broken away from the rest for some reason or other. It is worthy of note, too, that while we find almost endless variations in the seedling forms of triloba both in flower and foliage, this species has not, so far as I am aware, differed in either of these respects, though I doubt not a few really distinct shades would be gladly welcomed by all lovers of hardy plants, particularly if possessed of the size and vigour of the plant under notice.

IRIS STYLOSA.

Another instance of a hardy and free-growing perennial, which requires slight protection simply because its lovely flowers come in the depth of the winter season. They are rarely noticed till ready to expand, nestling among the deep green and elegant tufts of leaves. In planting, it would be well to place it so that it may be given the protection of a handlight or frame at flowering time, always admitting plenty of air by placing the light on pots. In rich sandy loam it grows freely, and some make compact tufts; and those who have grown it should endeavour to find room for one of the most lovely of the entire family. The flowers are slightly fragrant, of an exquisite sky-blue, and the plant is adapted for flowering in a cold house in pots where its beauty may be seen to greater advantage than in the open ground at this season of the year. Happily, it is one of the cheapest Irises, a decided recommendation to all who require something of exceptional merit.

TRILLIUMS.

All who are desirous of enjoying the charms which these present in the spring months should secure strong roots and plant them as soon as a favourable opportunity offers. It is an undeniable fact that the majority of early spring flowering plants are better for being planted in the early autumn, and these Trilliums are by no means exceptions to the rule. Their requirements are simple; peat, leaf soil well decayed, and sandy loam in about equal parts suit them admirably, to which a somewhat liberal addition of well decayed stable manure may be given with advantage. Above all things they must be given a cool, moist spot, such, for example, as may be found in positions assigned to hardy Ferns, from which flowering plants invariably are excluded—a state of things somewhat difficult to understand, especially as these places often furnish the conditions in which so many of our choice hardy plants delight, and these Trilliums in the moister parts of the hardy fernery would be suited exactly, and equally so the Hepaticas, *Helleborus niger*, Wood Anemones, and others. The most effective of the Trilliums are the

varieties of grandiflorum, notably maximum and præcox. Apart from these are erectum, also called atropurpureum, and the dainty erythrocarpum, which latter has white flowers with rose spots at the base of the petals internally, which render it very conspicuous. There are several other species, but these are the most worthy, and all require similar treatment.

SISYRINCHIUM GRANDIFLORUM.

One of the daintiest of all spring flowers, charming in large tufts in consequence of the numbers of flowering stems which issue from amidst its grassy leaves. It is singularly effective when in flower, and in spite of its apparently delicate and fragile nature is hardy, and far more enduring than may be at first sight imagined. When fully established it attains a foot high, and its pendant silky purple flowers are very pleasing. A deep bed of sandy loam will grow it to perfection, and if given a spot sheltered from high cutting wind so much the better. It has a most delightful companion in the pure white variety, which happily is equally free flowering and hardy, and both will be better suited on the rockery in sheltered spots than among the general collection in the border.

BRAMBLES.

HAVING seen *Rubus laciniatus* fruiting most abundantly for many years at Worksop Manor under the care of Mr. Sutton, and for several years at Oakbrook under Mr. Woodcock, as mentioned in the editorial footnote on page 547, and having had a row of it under my own charge at Elford Hall, where the fruit is highly esteemed, and required as regularly whilst in season as Raspberries, Strawberries, and Currants in their season, I think this particular *Rubus* is fully entitled to all the praise bestowed upon it. One of my predecessors—either Mr. Fairweather or the late Mr. Cunningham—planted it at Elford, and it has always justified all that has been said in its favour, and that being so, I never disturbed that row, although it occupied a position on a valuable south border, where, being only a Bramble, it looked out of place; but this position, I think, had something to do with its fruitfulness. The long strong canes annually produced were well ripened. I understand that the row is now removed to another part of the garden.—J. UDALÉ.

I FEAR I cannot give any reliable authority for stating my belief that the Parsley-leaved Bramble (*Rubus laciniatus*) was an English raised variety. I have a vague idea that I was once told it originated in the nursery of Messrs. Fisher, Holmes & Co., Handsworth, Sheffield, but I cannot recall to mind by whom. All I know is that I have heard several times it was an English and not an American variety, and probably the distinctive character of the plant and its adaptability to our climate, as compared with other American Brambles, helped me in the belief I expressed that it was of English origin. If my note be the means of eliciting something definite I shall be glad I opened out the question, for it may as well be settled now as hereafter.—F. BOYES.

WITH me the Parsley-leaved Bramble bears an abundance of large, handsome, juicy fruits, and is a very rampant grower. I have found that however carefully it is planted and treated afterwards that it stands still for two years, and this may account for the difference of opinion as to the merits of cultivated Blackberries. We train them over an arch of curved poles, and pruning and training consists of cutting out the old wood that has just fruited and tying the young in its place. This is a very unpleasant task, as the branches are a mass of thorns and get entangled together, and also in the assailant's clothes. If there was much of it to be done a leather apron would be a desirable addition to the gardener's wardrobe. However, I think it is well worth growing until a less shiny and otherwise equally good variety takes its place. The fruit makes a very fine preserve.—WALTER KRUSE.

WANTED, A PUBLIC HALL FOR HORTICULTURE.

SURELY it is inspiring to everyone when they see the exhibits of their countrymen standing boldly up and distancing foreign competitors. It should be known that every variety of fruit, flowers, and vegetables of worth that can be found upon the earth is brought to England. In every instance we grow them better than where they are indigenous. Of course the varieties are numerous, and it becomes a national necessity to weed out the inferior and to record the superior, and in this the Royal Horticultural Society has done incalculable good.

It is remarkable (and may be compared to the moral work and generosity of some, which is unrecognised during life) that scarcely any one knows the Society's worth, and those that do fail to promulgate the fact. The English by sheer intelligence have considerably improved nearly every production for the sustenance and happiness of the public. These have gone forth to every part of the world, and if it were possible to sum up the good it would be found that horticulture has done more to benefit the human race and make England eminent than any other profession, and, although much has been done to comfort and strengthen the body and cheer the heart of man, there is an endless amount still to do.

His late Royal Highness Prince Albert certainly made sure that he had secured a noble home for the Society, but it is at this moment, from no fault of theirs, without a floor or roof to call its own, yet now even, in lodgings as it were, the Society is leading horticulture and doing enormous good—agriculture owes them a heavy debt of gratitude. When we read of a patriotic lady in Philadelphia, evidently an admirer,

and anxious to forward horticulture in America, bequeathing £40,000 wherewith to build and maintain a hall of horticulture in that city, we feel it is retrogression on the part of the British in not possessing one long since to carry on one of the greatest sciences of the nation. There are many amongst our wealthy who in their time have enjoyed an immense amount of happiness, luxury, and contentment from their gardens, who we believe will follow the noble example of this estimable and generous American lady, and immortalise their name by securing and presenting the freehold of a suitable site for that most necessary institution—to hold their meetings, shelter their library and the Council who so nobly carry on the work.

There are plenty of central sites which would answer admirably, and as soon as the freehold is secured we are ready to subscribe £25, and we are quite sure the Secretary, Rev. W. Wilks, would be delighted to hear of others doing likewise.

We hope to live to see the day when we have a hall worthy of our great nation, and that the Committee of the National Chrysanthemum Society, the members of which number well nigh 1000, and whose work and exhibitions are of great importance, and stand pre-eminent with that flower, may be invited, and see their way also to hold their shows and meetings in this building, and all special Societies, such as Rosces, Dahlias, Auriculas, Carnations, &c., also the Gardeners' Benevolent Society, Gardeners' Orphan Fund, and Gardeners' Provident Society, in fact all societies pertaining to horticulture, have the same privilege, and thus avoid expensive hotels and other public resorts. This building we picture in our minds, and hope some day to see in reality.—HENRY CANNELL & SONS.

[We have received another communication from Messrs. Cannell on this subject.]

THE NATIONAL CHRYSANTHEMUM SOCIETY.

THE midwinter Show was held on Wednesday and Thursday January 8th and 9th, in the Royal Aquarium, Westminster, and notwithstanding the exceptionally unfavourable character of the season for late Chrysanthemums the competition was keener than usual, and the quality of the exhibits also better. Cut Chrysanthemum blooms were in the majority of cases fresh and bright, Primulas and Cyclamens were admirable, and the groups of miscellaneous plants all that could be expected at this time of year. There can be no question about the usefulness of Chrysanthemum flowers at Christmas and in the early part of January, because flowers of almost every kind are valuable then, and greater quantities of them, especially of the white and yellow varieties, will be found in the London markets than of any others. Still it is strange that so few really late varieties are obtained, though if Mr. Kipling's system is pursued they are not wanted, as any of the ordinary varieties can be had in good condition throughout the winter. Some of the most successful exhibitors in the Chrysanthemum classes were Mr. R. Owen, Maidenhead; Mr. Kipling, gardener to the Earl of Lytton, Knebworth; Mr. G. Bolas, gardener to H. Chandos Pole, Esq., Hopton Hall, Wirksworth; Mr. J. Brown, gardener to Mrs. Waterlow, Great Doods, Reigate; and Mr. Taylor, gardener to Sir John Lubbock, Bart., M.P., High Elms, Farnborough.

In the Primula classes Messrs. Carter, Newell, Mursell, and Dr. Phillips were the prizetakers, while with Cyclamens Messrs. W. Clarke, May, Phillips, White, and Carter were successful.

The Floral Committee held a meeting on January 8th, at 12.30 P.M., Mr. R. Ballantine in the chair, the following members being present:—Messrs. E. Sanderson, H. Cannell, G. Gordon, C. Gibson, L. Castle, J. Mardlin, W. Holmes, and R. Dean. Very few novelties were submitted, but Mr. E. Beckett, Aldenham House Gardens, Elstree, showed blooms of a Japanese Chrysanthemum named Mrs. H. Waterer, the blooms of a rather dull white, large, with broad florets. Mr. R. Owen also sent a Japanese variety named Kioto, bright yellow, like Mr. H. Cannell; but as these did not appear to be in their best condition the Committee requested the exhibitors to show them again. Several new Primulas were examined, and a certificate was awarded for a single variety named Progress (Messrs. H. Cannell & Sons), the flowers well formed, extremely stout in texture, and a rich crimson colour.

A conference was held in the Board-room of the Royal Aquarium at 6 P.M. the same evening, Mr. R. Ballantine in the chair, when there was a capital attendance. Mr. Kipling read the following paper, which induced a very interesting discussion, followed by a hearty vote of thanks to the reader:—

ARE CHRYSANTHEMUMS WANTED AT MIDWINTER?

THE question I have to submit for your consideration, Are Chrysanthemums wanted at midwinter? might well be answered by asking another, and correlative question, Are flowers wanted at midwinter? But it will probably be advisable to set forth the reasons why I consider that the answer should be in the affirmative. There are few people, I imagine, who have a taste for flowers, and thoroughly appreciate them

that would deny the necessity for having them in abundance at a season of the year which includes the festivities of Christmas and the New Year. At that season, as so well known, there is the greatest demand for flowers, and it is also a matter of common knowledge that they are then very scarce and most difficult to be had. This being the case, flowers are at midwinter appreciated as flowers irrespective of their names. Consequently Chrysanthemums, if they can be had at that season, are not likely to prove less welcome, or to be less appreciated by the general flower lover than the flowers of any other group of plants that could be mentioned. This is looking at the question simply from a common sense point of view. We might, however, look at it from another, and sentimental standpoint that, perhaps, from which the true lover and enthusiast of the Chrysanthemum would view the matter.

Most individuals have a taste—sentimental if you will—or hobby for pursuing some particular object, and as taste is not arbitrary, they have a perfect right to follow the bent of their tastes and inclinations, so long as they do not interfere with other people. Well, the Chrysanthemum enthusiast has a taste and hobby for the cultivation of this particular flower in its many phases, and I have no doubt, were he asked the question, Are Chrysanthemums wanted at midwinter? he would promptly reply Yes, and add, perhaps, at any other time that they can be had. He would, I venture to say, be perfectly justified in his answer and opinion, notwithstanding what a few individuals may say about Chrysanthemums not being wanted at this season or that season.

For my part, I can say that their flowers are appreciated at all seasons of the year, even to all the year round, which I have in my practice more than abundantly proved to be possible, but, perhaps, not generally quite desirable. However, at no season of the year do we find them so acceptable, so useful, and to fill so great a void as from the beginning of December to the end of January, or even later, a period of the year when there is a great dearth of other flowers, and those available are mostly forced, which are produced at considerable cost and last but a little time in good condition in a cut state.

It is here, then, that the usefulness of the midwinter Chrysanthemums is clearly apparent. They step into the breach as it were, and supply a felt want, and I claim consideration for them on grounds other than those of a sentimental character. They indeed fill a unique and useful position amongst winter-blooming plants, and from them a general demand for flowers can be met and supplied. The midwinter Chrysanthemums have another, and not the least, claim to our attention. Their cultivation, as compared with those grown for autumn decoration and for exhibition, is very simple, very inexpensive, and require from the grower only a tithe of the labour and watchful care the others demand from him. The cuttings are struck late, are a very little time on hand before they can be finally potted off, and the pots plunged to their rims in some cool half-shaded spot for the summer, and where in the hottest and driest of weather they require water only once a day, and on dull days none whatever. As ordinary decorative bloom only is the object sought there is no anxiety about the time the buds shall be taken, no thinning out of buds and shoots, and no feeding up with liquid manures as in the production of a few fat blooms. They will stand out of doors to the latest date possible without being injured even by a degree or two of frost, and when housed the accommodation of the coolest structures meets their requirements. Indeed, the Peach houses or the latest vineries—where low temperatures are necessary for resting the Vines and Peach trees are the best places for housing and retarding late Chrysanthemums up to the time it is necessary to push them into bloom. When this period arrives a little warmth becomes necessary, and to this they respond gratefully. Lastly, I know of no class of plants that give so large a return for the labour bestowed, the space occupied while under glass, and the little fuel needed in their production as these midwinter Chrysanthemums.

Not the least point in the favour of the late-blooming Chrysanthemums is the long keeping qualities of the blooms, and their capability of enduring close packing and long journeys. With ordinary care in packing they will, on reaching their destination, come out of the box as bright and fresh as could possibly be desired. Of course, the long keeping quality of the blooms is to a certain degree common to all the sections, and under all phases of their cultivation. But I find this quality in the flowers greatly emphasised in the midwinter blooms, and this, no doubt, is due to the plants having been grown under a natural system and under the hardest conditions possible, thus giving to the flowers a toughness and greater substance of petal. Damping of the blooms is hardly known among them, and we are therefore saved from the annoying and tantalising heartaches experienced by the exhibition bloom grower at seeing his brightest and fondest hopes, which are centred in his biggest and fattest of blooms, crumbling away day by day. With reference to the long keeping of blooms, I may mention that my noble employer writes me to send her nothing but Chrysanthemums, as no other flowers come to hand in so fresh and bright a condition or last so long. They invariably retain their freshness from a fortnight to three weeks after being sent, and I would like to ask what other cut flowers, except the Christmas Rose, will endure a two-days confinement and transit across the Channel, and yet come out fresh and bright and last for a fortnight or longer?

So much for the usefulness, and I might say the importance of the midwinter Chrysanthemums. A few remarks on the varieties that I have found to be the best to grow for the production of flowers at that season may not be uninteresting. There are three points or qualities

essential in a midwinter or late Chrysanthemum. The first point is its lateness to bloom, which should be natural to and inherent in the variety. Secondly, it should have a free habit of growth, and be a very free bloomer, as labour would be thrown away on a variety that would not yield liberal and adequate returns in the shape of flowers. Thirdly, the colour of the flower should show up well under both natural and artificial lights. Most of our floral decorations at this season of the year have to be seen under artificial light, colour in the flowers is therefore of some importance, and those colours which come out well under that light are the most valuable. Whites, reds of different shades, and yellows, including deep bronzy oranges, are the best colours, while purples, lilacs, and their several shades are the worst for the purpose.

The varieties which I have found to fulfil the several conditions therein enumerated are *Etoile du Midi*, Kämpfer, M. C. Hubert, Meg Merrilies and its sports Ralph Brocklebank and Countess of Lytton, Ceres, Mrs. C. Carey, Ethel, Yellow Ethel, Thunberg, Boule d'Or, Moonlight, Gloriosum, Mrs. H. Cannell, and Golden Gem among the Japs; Boule de Neige, Snowdrop, Madame Sentir, and one or two others among the reflexed and Pompon sections. In the section of the single varieties will be found some that are admirable for the supply of flowers at midwinter work. Hitherto this section has not made much advance in general favour, possibly because the Japanese varieties have been more attractive and have elbowed them out of the way at a time when blooms are so very plentiful early in the season. I believe, however, the single Chrysanthemum's most useful and proper position will be found as a midwinter flower. Their free blooming and the long-lasting qualities of the flowers are not surpassed by any others, and they have in a cut state, and when arranged in vases, an elegance and grace all their own, and they can be looked upon at the winter season, not as Chrysanthemums, but as various coloured Marguerites. Some years since I bought the set of twelve, the first, I believe, Mr. Cannell sent out, and each year has proved more and more their value for midwinter blooming. This season they did not commence to bloom till the beginning of December, and they have been a perfect mass of flower up to the present date. The best varieties of the twelve are Mrs. Langtry, pinkish white, very free; Magenta King, bright purplish rose; Canariensis, terra cotta, very elegant; Brunette, brick red and orange, very free and useful in a cut state; Ellen Terry, Mrs. Killock, Monte Carlo, and Gus Harris; the two latter are very compact in growth and make excellent pot specimens.

A question was next submitted to the meeting for discussion—namely, "In what way can the interest and attractions of Chrysanthemums be increased." This led to the expression of numerous opinions, but the majority seemed to be in favour of extending the classes for plants, groups, and floral decorations. Groups for effect only were also advocated, and some were in favour of classes for naturally grown blooms, shown with their stems and foliage. A vote of thanks to the Chairman concluded the proceedings.

CHRYSANTHEMUM NOTES AND REMEMBRANCES PAST AND PRESENT.

THE year just closed and the present year will henceforth be notable periods, as being the time when Englishmen decided to celebrate the centenary of the introduction of the Chrysanthemum into England. But whether or not it is exactly one hundred years since this popular favourite became established amongst us is, I think, a point on which opinions may differ. Loudon, in his "Encyclopedia of Gardening," published in 1824, gives the date of its introduction 1764; the "Cottage Gardeners' Dictionary" also fixes the same year. Mr. Joseph Sabine, in his first paper in the Transactions of the Royal Horticultural Society, published in 1822, infers that it was known in England before, and quotes several authorities on the subject; but he adds, "but the credit of their first reappearance, as far as their present existence is concerned, belongs to M. Blancard, a merchant of Marseilles, who in 1789 imported three different plants from China." He further tells us that one of these, the purple, was transmitted to this country from France in 1790, hence I suppose it is why it has been thought proper to celebrate its centenary in two separate years. Mr. Joseph Sabine's writings on the Chrysanthemum has formed the basis of history for all subsequent authorities. Even Mr. A. H. Haworth, whose classification of forty-eight varieties, published in 1833, refers almost every variety to Mr. Sabine's papers in the Horticultural Transactions. Writers of to-day refer to and repeat his work for the interest and benefit of the present generation, therefore we that admire the flower of to-day should spare a thought of gratitude to him who nearly seventy years ago laboured so assiduously, attentively, and minutely for the public good. Who can tell but from the exertions of the Royal Horticultural Society, so ably assisted by the enthusiasm of their Secretary for this favourite flower, whether we to-day should have been able to have had and enjoy the magnificent displays that are now to be seen in almost every hamlet of Great Britain?

Both amateur and professional gardeners soon learnt its beauty and usefulness to brighten the waning days of departing autumn, which gave an impetus to its cultivation. Several nurserymen and a few private growers began to grow collections, and as new varieties could be procured added them, but none made such a study of them or grew so many varieties as Mr. John Salter. Year after year he laboured on introducing many new and excellent seedlings, some of which are now amongst the best of the present age, especially in the incurved and reflexed sections. Several societies were started for the encouragement and

further development of this flower; although not like those of the present day, they were very pleasing and attractive, many of them having done much to stimulate improvement both in plant growing and cut flowers. I well remember my first impressions on going to the Stoke Newington Show in 1869, and seeing the neat and prim boxes of blooms staged there. Although I became acquainted with the border flowers ten years before that time, and had grown a display in pots five years previously, I had not seen an exhibition. Some of these early societies encouraged pot culture, some going in for mere size of plant, while others mainly displayed medium-sized plants with flowers of extraordinary quality. Brixton was notable for the latter. At Southampton and Birmingham much larger plants were staged. I think it was in 1878 or 1879 I saw some magnificent plants at Southampton 5 feet through. There were at this time several good provincial exhibitions throughout the country, but nothing like the number of the present day.

Up to about the year 1880, generally speaking, the Chrysanthemum from an exhibitor's standpoint was but indifferently grown in private gardens. Some few places around London and large provincial towns where exhibitions had given stimulus to their culture they were well grown; but the Japanese was not so numerous as now, or as well known, and the grouping system which has been one of the most encouraging classes for home displays that ever could have been conceived, was scarcely adopted at any exhibition. Trained plants and cut flowers were the principal features. Formerly no groups of table plants, Primulas, Cyclamens, Solanums, baskets and epergnes of grasses and autumn leaves were thought of. The timely introduction of all these small features lends beauty and usefulness, while the Japanese blooms add brightness of colouring and diversity of shape almost inconceivable. Although the Japanese had been known from 1861 or 1862 they can scarcely be said to be in fair cultivation for at least ten years after. I cannot tell to whom the credit is due for bringing them before the masses, but I think none more so than to the late Messrs. Jackson and Sons of Kingston and Mr. F. A. Davis of Surbiton, who was for several years the President of the Kingston Chrysanthemum Society. Mr. Davis bought every new variety as they came out, and him and Mr. Douglas I well remember exhibited several times in this class at the Royal Horticultural Society, when that Society offered prizes for them. Mr. Davis has always been a great lover and patron of the Chrysanthemum, and has never once refrained from competing in the challenge vase class since the formation of the Kingston Society some fourteen or fifteen years since. Whatever may in the future be the outcome of the Kingston Show, it must be admitted by all exhibitors who have had the pleasure of visiting its exhibitions that it has sown the seed of usefulness to younger societies by the introduction of several features now common to shows, but not generally known before it was adopted there. The first and most important feature introduced here was when substantial prizes were offered for groups of Chrysanthemums in a given space. Although these groups were a little tall at first, they subsequently became dwarfer through the happy idea of Mr. Orbard. The attractive feature of the groups there led to their adoption in almost every exhibition, and I have admired this season in small out-of-the-way provincial towns splendidly dwarf and pleasing groups; those staged at Halstead in Essex were magnificent. I also saw some good ones at Sudbury, Suffolk, and Newport, Isle of Wight, and at home what better and more attractive feature was there either at the Crystal Palace or the Aquarium than Messrs. Laing & Sons', also the Blackheath groups. While this feature has necessarily improved at the exhibition tent they have equally improved the plants for the home display, the dwarfing system has become more generally understood, and flowers and foliage now supply the place of hideous stakes and lanky stems of formerly. The display of table and other plants now so often found running in a line down the centre of each table between two rows of boxes of cut flowers I think originated at Kingston, and perhaps for these and several other smaller minutiae the thanks of all is due to Mr. Puttock, a man of vast experience in all horticultural arrangements.

The offering of the several valuable challenge prizes was undoubtedly the making of Kingston Show, but while it added interest and fame to Kingston it has done much to stimulate the growth of the Chrysanthemum throughout the length and breadth of the land. The Japanese varieties were known, grown, and exhibited at Kingston before anywhere else. They were included in the class for the challenge vase, and outside growers had to grow them to compete. A friendly rivalry existed between the growers of Kingston and Wimbledon and the growers of Liverpool. The Liverpool growers, to their spirit, courage, and merit, be it said, they came and won. I think I am right in saying that before the Kingston challenge vase was offered scarcely a Japanese flower was grown around Liverpool. I well remember Mr. Molyneux's admiration of Bouquet Fait, M. Ardene, and other Japanese blooms staged in the all-England challenge prize stand at Southampton in 1879. Also I remember his telling me that he would beat me the following year, and so he did; but Kingston secured him through it, and some magnificent blooms. What a change has come over the Japanese section since then. Madame Bertie Rendatler was a good flower in 1879, but what a contrast between that and *Etoile de Lyon* in 1889.

The incurved varieties have not varied as much. The fine old Queen family is very old, and holds its own against all. What fine ones in days of yore Mr. Shrimpton, gardener at Roehampton, used to grow. Excepting sports I think we have only had one new one for years—viz., Jeanne d'Arc. Sports are now becoming plentiful. Grand additions

we have in Miss Haggas and Violet Tomlin. No person need be hard up for a box of twenty-four distinct varieties without falling back on small sorts. I do sincerely hope that all societies, no matter how large or small, will in future offer prizes only for distinct varieties. To ask for duplicates is a weakening feature in any stand or exhibition. Every interested person wishes to see a complete collection distinct. When duplicates are allowed very much of the interest and purposes of the exhibition is shorn. We have plenty of varieties and plenty of good exhibitors that are ready to exhibit if framers of schedules will only ask for six, twelve, eighteen, twenty-four, or forty-eight distinct varieties, as the case may be.—J. W. M.

CHRYSANTHEMUM EXHIBITIONS—A PLEA FOR SMALL GROWERS.

Now that thoughts are directed to the next year's shows, I have thought it to be well to advance the claims of the small grower, whose chances are becoming in some districts, from the increasing competition, almost obscure. The ambition of the small grower is, in many instances, quite as keen as that of the large cultivator, and certainly deserves notice. I am aware that at most Chrysanthemum shows there are small classes provided, and there are others where there is no such provision, and where it is so the smaller grower is not absolutely catered for. In this I am speaking from actual experience, for I had myself in small classes to meet men provided with much greater conveniences than I have. I do not wish in the least to complain, as the competition was fully in accordance with the stipulations of the schedules, but I am sure if a class could be set apart for those who kept one, or at most two gardeners, it would become as popular as those of larger numbers, and tend to increase patronage and enthusiasm. Fancy prizes, though appreciated by those fortunate enough to secure them, are, however, not required in meeting the claims here set forth, and societies not having framed their schedules for the next Chrysanthemum contests would confer a favour by such a provision on a section now in a minority. In giving expression to these views I am not prompted by selfish motives, but the fact of so many large establishments taking foremost places, the lesser growers' chances are thereby becoming extinct.—SMALL GROWER.

CHRYSANTHEMUM PRINCESS BLANCHE.

A SLIP of the pen on page 31 needs correction. The late variety which Mr. Stevens has found so useful from before Christmas to the present time is not named "Lady" but Princess Blanche. It was certificated two or three years ago at the January Show of the National Chrysanthemum Society, but in 1888 Mr. Stevens' plants were spoiled by the October frost, so nothing was heard of the Princess at Putney that year. He intends growing nine hundred plants of the variety this year. The plants now just over were never topped, but allowed to break twice naturally, then the terminal buds formed, and one bloom was retained on each shoot. The plants resemble small free half-standards from 2 feet to 2½ feet high.

ROYAL HORTICULTURAL SOCIETY.

JANUARY 14TH.

THE first meeting of the Committees for the year 1890 was held in the Drill Hall, James Street, Victoria Street, on Tuesday last, the time for the commencement of business being fixed for 12 noon. Prior to that the President (Sir Trevor Lawrence, Bart., M.P.) addressed the Committees in a short speech, thanking them for the services they rendered, which he stated were highly appreciated both by the Council and the Fellows generally. He was sure that they included in their several Committees the best authorities on the respective subjects that could be obtained, and the utmost confidence was felt in their decisions.

The number of exhibits was not large, but the Orchids formed a special and important feature, particularly the hybrid Dendrobiums from Burford Lodge, which were much admired. The hybrid Nepenthes from Chelsea and the Ferns from Edmonton also constituted interesting additions to the display. In the afternoon the Rev. W. Wilks read a practical and suggestive paper on "Winter Gardening," a number of Fellows assembling to hear his discourse.

FRUIT COMMITTEE.—At this early season of the year only a limited number of exhibits are expected. The most interesting, perhaps, and certainly the most unusual, was a Papaw Tree from Chatsworth bearing green and ripe fruit. There was a good attendance of members, including John Lee, Esq., in the chair, with Dr. Hogg, and Messrs. P. Crowley, P. Barr, J. Cheal, W. Denning, G. Norman, A. H. Pearson, G. W. Cummins, G. Cliffe, C. Ross, A. Watkins, W. Warren, G. Bunyard, H. Balderson, F. Q. Lane, W. Wildsmith, J. T. Saltmarsh, R. D. Blackmore, W. Coleman, James Hudson, J. Wright, and James Smith.

Mr. H. Morris, Glanafw Gardens, Taibach, South Wales, sent a very good Pine Apple, for which a vote of thanks was accorded. Mr. G. W. Cummins again sent a dish of the Apple named Remborough, in the garden of A. H. Smee, Esq. It resembles an enlarged form of the Golden Winter Pearmain, commonly called King of the Pippins, and though considered useful, no award was granted. Mr. Myles, Appley Towers, Ryde, sent a bunch of the Appley Towers Black Grape that was certificated in the autumn, also another seedling with large berries resembling the Morocco, a Grape of promise, which the Committee desired to see in March. Parents, Gros Colman and Alicante. Of the same parentage was a round white Grape resembling in appearance Mrs. Pearson, and of agreeable flavour. It was passed with the expression of a hope that it would be sent again next year. Mr. Miller,

gardener to Lord Folcy, sent from Ruxley Lodge, Esher, large boxes of Mushrooms from indoor and outdoor beds, and a vote of thanks was unanimously awarded; a cultural commendation having been awarded to Mr. Miller at a previous meeting for similar examples. He seems to be an expert in Mushroom culture. Mr. A. Dean sent specimens of Spanish Onions, both home-grown and imported, the latter 18 inches in circumference, the former smaller, but not regarded as less useful. A vote of thanks was recorded.

Mr. O. Thomas sent from Chatsworth a fruiting plant of the Papaw in fruit. The plant was in a pot. The character of the plant somewhat resembles that of a broad leaved Aralia. The stem was thick, and leafless to the height of about 3 feet, then came the fruits, which in shape and size were not unlike that of the Tree Tomato figured on page 15. They clustered closely round the stem to the length of a foot, some yellow, but most green, and had an ornamental appearance. The large leaves appeared above the fruit, but were withering. The plant was raised from seed last year. Whether the stem was cut and inserted in the pot for convenience of transit we did not ascertain. Dr. Hogg, in his "Vegetable Kingdom," says:—"The Papaw Tree (*Carica papaya*) is cultivated for the sake of its fruit, which is eaten when cooked, and has a pleasant sweetish taste. When young, it is generally used for sauce; and when boiled and mixed with lime juice, it is used as a substitute for Apples, to which in flavour it has a resemblance. The juice of the unripe fruit is a powerful and efficient vermifuge, and the powder of the seeds answers the same purpose. The principal constituent of the juice is fibrine, a principle hitherto supposed to belong to the animal kingdom and to the fungi. Water impregnated with this juice renders all sorts of meat steeped in it tender, and even the flesh of old hogs and old poultry fed on the leaves and fruit is thus made perfectly tender, but must be eaten as soon as killed, otherwise it will run to putridity. Even the vapour of the tree answers the same purpose, and hence people hang joints of meat, fowls, &c., in the upper part of the tree to prepare them for table." Doubts were, however, expressed as to whether the specimen exhibited was the true Papaw, or another species of the genus *Carica*. The Chatsworth tree was scarcely large enough for "hanging joints and fowls in," but all the same, the Committee were glad to see it, and a cordial vote of thanks to Mr. Thomas was recorded, and a cultural commendation recommended.

Several heads of Broccoli were brought from the trial collection of Chiswick, and three marks of merit were given to Early Penzance; the plants raised from seed supplied by Messrs. R. Veitch & Sons and Rutley and Silverlock. The heads were closer than those of Snow's Winter White, which was, however, represented in by no means its best condition.

FLORAL COMMITTEE.—Present: Dr. M. T. Masters in the chair, and Messrs. R. Dean, T. Baines, F. R. Ross, H. Herbst, W. Holmes, J. Walker, G. Nicholson, H. B. May, Henry Cannell, P. Blair, B. Wynne, Henry Turner, Charles Noble, George Paul, J. Fraser, R. B. Lowe, and W. C. Leach.

Messrs. J. Veitch & Sons, Chelsea, contributed a collection of pitchers of hybrid Nepenthes, representing over forty distinct forms (silver medal). Messrs. Barr & Son, Covent Garden, exhibited flowering plants of *Anemone fulgens*, *Crocus Imperati*, *Galanthus Elwesii*, *Narcissus minimus*, *Crocus Sieberi*, and *Crocus chrysanthus* in pots and pans. Messrs. G. Paul & Son, Cheshunt, showed plants of *Spirea astilboides* with feathery spikes of white flowers, and the black-spined *Arum sanctum*. Mr. H. B. May, Edmonton, had an interesting group of Ferns, for which a bronze medal was awarded. Messrs. H. Cannell and Sons, Swanley, showed a series of choice Primulas, and several were adjudged awards of merit, and a vote of thanks recognised the whole collection. Messrs. Walshaw & Son of Scarborough exhibited spathes and leaves of *Richardia aethiopica* (vote of thanks). Mr. O. Thomas, Chatsworth Gardens, sent several strong plants of *Amaryllis* (vote of thanks).

ORCHID COMMITTEE.—Present: Sir Trevor Lawrence, Bart., M.P., in the chair; Baron Schröder, and Messrs. De B. Crawshay, F. G. Tautz, T. B. Haywood, F. A. Philbrick, H. Ballantine, H. M. Pollett, J. Dominy, C. Pilcher, Harry J. Veitch, Lewis Castle, F. Moore, James O'Brien, E. Hill and A. H. Smee. A well attended meeting was held, and the exhibits were exceptionally good for this time of year. Sir Trevor Lawrence, Bart., M.P., exhibited a group of choice Orchids, several of which were certificated. Others were *Laelia Patini*, regarded as the same as *Cattleya Skinneri* (vote of thanks); *Dendrobium nobile Cooksoni*, bearing eight fine flowers, very distinct and beautiful (certificated February 14th, 1888); *D. nobile Tollyanum* in which the lip is turned the reverse way—namely, upwards; and *Laelia pumila* var. *El Spiritu Sancto*.

E. Ellis, Esq., Manor House, Wallington (gardener, Mr. A. Glover), sent a plant of *Lycaste plana* with over a dozen very dark flowers (cultural commendation). N. N. Sherwood, Esq., Dunedin, Streatham Hill (gardener, Mr. J. Jones), was awarded a vote of thanks for a dark variety of *Lycaste Skinneri* named *rubra*; the flowers of a deep reddish crimson. Messrs. Pitcher & Manda, East Dulwich, sent a plant of *Cypripedium Masereelianum* (C. Spicerianum and C. insigne Chantini) which was considered to be identical with *C. Lecanum* (vote of thanks). F. G. Tautz, Esq., Goldhawk Road, Hammersmith (gardener, Mr. J. C. Cowley), showed several varieties of *Lycaste Skinneri* and the pretty pale yellow *Cœlogyne lentiginosa*. De B. Crawshay, Esq., Rosefields, Sevenoaks, sent a plant of *Laelia Crawshayana*, much resembling a small variety of *L. anceps*. Mr. Harvey, Riversdale Road, Liverpool, showed a plant of

Lælia anceps with ten white flowers (vote of thanks). T. Slatter, Esq. (gardener, Mr. R. Johnson), Stand Hall, Whitfield, Manchester, had a plant of *Vanda Amesiana alba* with several spikes of white flowers (vote of thanks). Mr. P. Blair, Trentham Gardens, showed *Cattleya Trianae* albescens with seven flowers nearly white with blush tinted lips (vote of thanks). *Cypripedium Calypso* from Messrs. J. Veitch & Sons, were awarded a vote of thanks. It is the result of a cross between *C. Spicerianum* and *C. villosum* Boxalli, but it is much like *C. Spicerianum*.

CERTIFICATED PLANTS.

Dendrobium Juno (Sir Trevor Lawrence).—A hybrid between *D. Wardianum* and *D. moniliforme*, the growth resembling the former. The flower is of excellent shape, the sepals and petals broad, white, deeply tinged with crimson, the lip rounded, having a maroon centre, a yellowish tinge, a white zone, and a purplish marginal band. (First-class certificate).

Dendrobium Luna (Sir Trevor Lawrence).—A hybrid between *D. Ainsworthii* and *D. Findleyanum*, the pseudo-bulbs and growth resembling the latter parent. The flowers are about 2½ inches across the lip, nearly circular, but somewhat oval, creamy white, yellow at the base, with a few purple veins in the centre. The sepals and petals are creamy white, faintly tipped with purple, the petals slightly broader than the sepals. The flowers were borne on short racemes of three or four each. It appears to be a free-growing and free-flowering *Dendrobium*, and it is likely to become a useful Orchid. (First-class certificate).

Dendrobium Macfarlanei (J. Veitch & Sons).—A species from New Guinea, remarkably distinct, and a valuable addition to the list of cultivated *Dendrobiums*. The sepals are acute, tapering, rather more than an inch long, white; the petals are rhomboidal in form, 1½ inch long, 1 inch broad at the widest portion, and also white. The lip has an obovate central lobe, white; the basal wings white, with a few deep purple veins. The growth is somewhat fusiform, after the style of *D. thyrsoiflorum*, and the plant shown had two flowers. (First-class certificate).

Dendrobium nobile, *Burford variety* (Sir T. Lawrence, Bart., M.P.).—A peculiar and interesting variety of the *Cooksoni* type, but the rich crimson colouring of the lip is extended to the lower part of the two basal sepals, instead of in the petals, as with *Cooksoni*.

Dendrobium xanthocentrum (Sir Trevor Lawrence).—A hybrid, evidently partaking of the *Dendrobium Findleyanum* character in growth and flowers. The sepals and petals are spreading, white, tipped with purple; the lip flat, open, orange in the centre, with bands of white and pale purple. Free and good.

Primula Eynsford Pink (H. Cannell & Sons).—A pretty variety, the flowers large, of good substance, and a delicate pink colour. (Award of merit).

Primula Eynsford Red (H. Cannell & Sons).—Rich crimson flowers, freely produced in stout trusses. (Award of merit).

Primula Her Majesty (H. Cannell & Sons).—Flowers of great size and substance, pure white, with a deep yellow eye. Fern-leaved. (Award of merit).

Pteris serrulata gloriosa (H. B. May).—A graceful variety of a well-known useful Fern, a capital addition to the list of Ferns for decorative purposes. (Award of merit).

PRIMULA OBCONICA.

In establishments where large demands are made for plants suitable for house and conservatory furnishing, the value of the *Primula* under notice cannot well be overlooked, as it provides a decided change from the more generally cultivated Chinese varieties in the various purposes to which flowers and plants are applied. It certainly lacks the bright colours and bold flowers that characterise the most popular strains of *P. sinensis*, but this failing is counteracted to some extent by their free and continuous flowering. So far as I have been able to learn they have not been subjected to the hybridiser's attention as affecting variety of colour, although from a packet of seeds now plants may be secured of varying character both as to habit and shade of colour, but the latter only assumes a lilac of a more or less degree of intensity. For small vases they are capitally suited, as from their dense growth the soil is completely hidden, and the pots partially so from the recurving nature of the leafstalks.

Unfortunately for the plant its reputation is somewhat at stake, for it has been found by some persons of delicate skin to cause irritation after a slight touch with the hand, and is consequently greeted with much the same terror as that associated with the handling of a Nettle, by some ladies to whom these unfavourable symptoms have been related. However, this will concern the smaller amateur grower more than gardeners, and to either such objections can be ill afforded. For gas-lighted rooms it is invaluable, as it will withstand such unfavourable conditions better than the majority of flowering plants. Most people are cognisant of the injury done to plants by gas, and blooming plants in particular, for a season's growth is expended in a few hours when submitted to an atmosphere highly charged with gas. *P. sinensis* withstands the impure air to a commendable degree, but it cannot be said, I think, to have the same resenting quality possessed by

P. obconica. From these remarks it will be understood to be an excellent plant for town growers in particular, and to cultivators in general. Treatment accorded to *P. sinensis* is found suitable for the other in almost every detail.—W. S.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.

THE Secretary, in sending us the following balance-sheet, as audited on Monday evening last, remarks, he "does not think there is much cause for complaint." Nor do we, but on the contrary think there is much reason for gratification that the Institution is so well supported, and that it is doing increasing good to those who have toiled long in gardens and need assistance in the eventide of life.

STATEMENT OF THE RECEIPTS AND PAYMENTS OF THE GARDENERS' ROYAL BENEVOLENT INSTITUTION FOR THE YEAR ENDING DECEMBER, 31ST, 1889.

WESTLEY HALL GARDENS.

THE weather is not favourable for visiting gardens just now, nevertheless to escape from the smoke of the metropolis for a few whiffs of bracing air outweighs any losses of natural beauty, scenery, &c., one would expect from a visit to the country in the summer. The owners of the above gardens, R. Burrell, Esq., and Mrs. Burrell, take great interest in horticulture, sparing no expense necessary to produce fruit, flowers and vegetables equal to any. A happy man then must be the gardener, Mr. Bishop, who has had charge of these gardens four years, and they do him great credit. The garden is some distance from the house, and lies on the crest of a south hill, and the shrubberies are enhanced in beauty in summer by containing many flowering specimens. The houses are well arranged. The Peach range, in which the parasitical fungi have been eradicated, covers the whole length of the inside south wall of the kitchen garden, the back wall being covered with well trained trees, and the front being filled with standards in 11-inch pots. These succeed exceptionally well, and last year were much admired by all who saw them.

Two small stoves running at right angles to the Peach range are filled with specimen *Crotons*, *Dracænas*, &c. I noticed a good plant of *Scuticaria Steeli*, which flowered twice last summer, and is now again showing bloom. Two larger houses parallel to the small stoves comprised a greenhouse and stove, the former filled with the flowering plants, including a fine strain of *Primulas*, the latter being filled with fine *Adiantums*, some reaching 7 feet in diameter, *Davallia Mooreana* being extremely fine, together with *Crotons*, *Dracænas*, and a few *Orchids*. There is also a range of vineries, and flower houses, but they contain nothing of exceptional merit at this period of the year to call for mention; the Vines however, have been greatly improved.

The object of penning this was to give my ideas about the fungi, but when good examples of culture are seen they cannot be overlooked. For instance, Potatoes in pots are grown well and are much appreciated. Celery and Peas are more in demand than other vegetables; the former is extra good, and the secret of success is a good dressing of blood and fish manure obtained from the Westley Manure Works, which is applied at the earthing up and in the trench at planting time.

An outside south wall was covered with Peach trees which have been

almost entirely destroyed by the fungus. Nothing has been done specially to eradicate it, but of course now that Mr. Bishop has proved himself the master of this parasite no pains will be spared. The cause of his success he will explain in the *Journal* shortly.—VISITOR.

THE AMATEUR'S BEESTON GREENHOUSE.

A FORTNIGHT ago we directed attention to this greenhouse, and subsequently the annexed illustration and particulars arrived after a delay in transit. Messrs. Foster & Pearson say in respect to the structure, "Having received many inquiries whether glass sides and ends can be adopted to our well-known 10 feet and 12 feet frames, we beg to introduce the above new house, which will, we believe, prove a great step in advance of any previously offered to the public. The roof lights slide up and down, and are secured by a very simple arrangement, at intervals of 3 inches, so that they cannot be lifted by the wind. The side lights are fast, as air blowing directly upon the plants is generally considered injurious, and side ventilation is here given by our registered iron ventilators placed under the sill, so that the air is warmed by passing over the pipes as it enters the house. One door is provided for each house unless otherwise ordered. The lights can be at once removed if necessary to expose the contents of the house. The iron rafters which span from sill to sill give the "Beeston" houses great strength, and there is no danger of sides or roof giving way after a few years' wear.

They threw up a few spikes through the summer; in the autumn of 1889 some had four and five spikes, mostly with five or six flowers each; one had seven, which I had never seen before, as I think five is the general number, although I have several at the present time with six each, and six and seven spikes to an 8-inch pot, which I think is not so bad considering the condition they were in two years ago this spring. They have not been rested at all since I had them with the exception of withholding water from the roots for about two weeks at the end of November. They were kept in the same temperature as they had been growing in before, they were syringed every day with the rest of the plants in the stoves to prevent flagging. The soil that I found best for them is nearly three parts good loam, one part leaf mould, with plenty of river sand and a few lumps of charcoal to keep the soil sweet. Some use manure, but I do not; I would much rather use a little soot, giving them liquid manure about twice a week when they are growing, also a little guano water. It is essential in good culture to provide good drainage, firm potting, and careful watering; to keep the soil sweet with plenty of heat and a moist atmosphere, also shading from hot sunshine. *Eucharises* are not much troubled with insects. Thrips are their worst enemy, which can generally be kept down by syringing, although mealy bug is apt to be troublesome at times; they can, however, be easily removed by sponging the leaves.—W. JONES, *Dorset*.

[Some excellent flowers of *Eucharis grandiflora* accompanied this letter, well substantiating our correspondent's remarks as to the success

FIG. 8.—THE AMATEUR'S BEESTON GREENHOUSE.

The woodwork is constructed of the best red deal, well seasoned, and painted three coats; 21 oz. sheet glass is sent packed in crates or glazing, and all parts are carefully numbered, so as to be readily fixed by any ordinary workman. The height from floor to top of roof is 8 feet 1 inch, and the woodwork of sides is 2 feet 3 inches high in the houses 12 feet wide, and 2 feet high in those 10 feet wide. If required for plant houses they can be filled up with stages instead of beds as shown."

These elevated frames are made in various sizes, and a glance at the figure will suffice to show how well adapted they are to various cultural purposes.

EUPHARIS GRANDIFLORA.

I HAVE been greatly interested in the notes that have appeared respecting *Eucharises*, so I thought I would just say a word as to the treatment I have found to suit them. In the first place the plants that I started with did not look promising, as they were old bulbs given to me by a friend two years ago that he had condemned to the rubbish heap. I could not say whether they had the *Eucharis* mite or not, all I know is that the bulbs were decayed half way through, had not a root and scarcely a leaf. The first thing I did was to pull all the decayed portions from them. I then prepared some clean 6-inch pots, and placed four or five of the largest bulbs in each, besides a few of the smaller ones. They were then plunged in a hotbed about 75°, besides top heat, which was kept from 75° to 85° in the day, from 65° to 75° at night; they soon began to show signs of life. I did not water them the first week or two, but syringed them morning and afternoon, kept them shaded from hot sun, as I find they will not stand much sun heat even when established. I always shade them in the spring and summer from 10 A.M. till about 3 P.M., syringing them well at closing time. I had a few spikes of flowers from them the first autumn, and in the spring of 1889 I transferred the bulbs to 8-inch pots without disturbing them, as I think it a great mistake to separate the bulbs when in good condition.

of his culture. Flowers also were enclosed of *Kalanchoe carnea*, fine heads and very fragrant. Mr. Jones says he has twenty plants in flower from seed sown last March.]

REVIEW OF BOOK.

English Vegetables and Flowers in India and Ceylon. By DONALD McDONALD. London: John Haddon & Co., 3, Bouverie Street, Fleet Street, S.E. 1890.

THIS is a neatly bound well printed manual of sixty pages, containing a large amount of information likely to be useful to residents in British India. Inquiries are often made for a handy guide to the essentials of gardening in tropical countries, and more especially with regard to India, and the requirements of those seeking information will be exactly met by the book under notice. Chapters or sections are devoted to "The Climate and Physical Features of India," "The Soils of India," "Formation of a Garden." An admirably suggestive calendar is given adapted for Northern, Central, and Southern India. An elaborate table "showing the proper months to sow and plant English vegetables in the plains," also conveys a good deal of information in a small space. Then we have alphabetical arrangements of the best vegetables and flowers, with the quantities of seed to be sown, and the general cultural treatment. Particulars of the hill stations and garden cultivation in Upper India, notes on Ceylon, lists of ornamental foliage plants, notes on lawns, Roses, bulbs, English fruits, and a variety of useful information that cannot fail to be appreciated. We cordially commend the book to any readers who are meditating a journey to our Empire in the East.

A BULLFINCH ANTIDOTE.

IN reference to the request on page 27 the following are the proportions in which I use the dressing I find effectual:—To 30 gallons of soft

water I put 1 peck of soot, 1 ditto of lime. I dissolve 3 lbs. of soft-soap, 3 of Gishurst compound, in warm water; this I place with the former; the whole is then strained through a piece of coarse canvas, and, as before stated, applied to the trees with the syringe. This will be found sufficient to dress a great number of trees. I am happy to say that on looking round the garden I found very little to complain of. A bud here and there was missing on the young growth, but this was where the dressing had not touched. I was sorry to find that nearly all my young Lettuce plants were missing, or only the midribs were left; also that the bird in question had actually cleared a Beurré Clairgeau Pear tree of its buds. Such a thing I cannot remember having seen before. Have any of your readers experienced it? I have known these birds strip Green Gages of their fruit buds, but never Pears. The buds of this particular Pear are very soft, and this would account for the birds attacking it. As I stated, I have always been a friend to birds but if they are going to serve me like this I am afraid we must dissolve partnership, for I really cannot stand this. They are becoming very numerous in this neighbourhood.—T. A. C.

FRUIT FORCING.

FIGS.—Early Forced Trees in Pots.—The growth being now somewhat advanced, the temperature should be increased to 60° at night and 65° by day by artificial means, and 70° to 75° with sun heat, commencing to ventilate at 70°, closing at 75°, and if the temperature rise 5° to 10° it will be an advantage, provided it be due to sun heat. Avoid a high temperature by artificial means, as the sturdier and shorter jointed the young shoots can be kept the greater will be the chances of a satisfactory early crop. The trees will need to be syringed twice a day, in the morning and again at closing time, but avoid a confined saturated atmosphere in dull weather, but damp the paths and walls when they become dry. As the fermenting materials settle firmly about the pots add more fresh leaves, bringing them nearer to the rims of the pots, taking care that the heat about them does not exceed 70° to 75°. Water the trees as required with weak liquid manure, and place some turves about 2 inches thick, grass side downwards, so as to reach over the rims of the pots and form a cavity between the turves and stems of the trees. These should be watered with weak liquid manure, so as to keep them moist, filling the space between the turves and stems of the trees with decayed manure.

Fig Trees to Ripen Fruit in May.—The house containing planted-out trees should have been already started, but there must be no further delay. The border being thoroughly watered, repeating so as to insure its thorough moistening, after which the surface may be mulched with short manure about 2 inches thick, placing it rather thicker near the stem so as to encourage the roots to extend. The surfaces of the house and trees will require an occasional syringing, the night temperature being 50° and 55° from fire heat by day, and from 60° to 65° with sun heat, ventilating freely from that temperature. Well moisten the mulching.

VINES.—Early Forced Vines in Pots.—As soon as the fruit is set attention should be given to thinning, commencing as soon as the berries are fairly swelling, watering copiously with liquid manure, and damping with the same in the afternoon. Encourage growths above the fruit, yet only as much as can have exposure to light. The soil should be surface dressed with short manure, and when roots are emitted freely from the "collar," some turves may be placed around the rims extending a couple of inches over the pots, so as to lie on the fermenting bed of leaves. The temperature may range from 65° to 70° at night, 70° to 75° by day, and 80° to 85° from sun heat, admitting air from 75°, and closing early, so as to raise it to 85° or 90° with sun heat, damping available surfaces at closing time, or early in the afternoon. Syringing the foliage ought not to be practised, as there is always danger of the water leaving a deposit on the berries, which spoils the appearance of well-finished fruit.

Early Houses.—These will now require great care in ventilating, so as not to admit draughts of cold air, which injure the foliage. Disbud and tie the shoots down before they touch the glass. In stopping do not confine to any given number of joints beyond the bunch, but extend it so that an ample and even supply of foliage will be insured, but do not crowd the house with more foliage than can be fully exposed to light. Remove all superfluous bunches, overcropping and overcrowding of the foliage being most adverse to satisfactory results. When the flowers are open maintain a temperature night and day of 70° to 75°, and a rather drier atmosphere, not allowing the fermenting materials to decline at this critical stage, but preserve a good heap of Oak leaves and stable litter in the reserve ground, to admit of a supply being obtained as required.

Houses Started at the New Year.—The Vines ought to have the inside border thoroughly moistened by repeated applications of liquid manure at a temperature of 90°. It is more conducive to a speedy and good break than anything short of the employment of fermenting material, which not only affords warmth but gives a moist ammonia-charged

vapour highly conducive to rapid vegetation. The outside borders should have a good supply of fermenting material, but if this cannot be done afford a good supply of dry litter or fern, so as to modify in some measure the chilling tendency of cold rains and snow. Sprinkle the Vines frequently; maintain a temperature of 50° to 55° at night, 60° to 65° by day, ventilating freely above 65°. The rods and canes of young Vines should be slung in a horizontal position to secure a regular break.

Houses of Late Grapes.—These may now be removed to a dry room where they will keep quite as well as if left on the Vines. Cut the bunches with as much wood attached as can be spared, and place the stems in bottles filled with soft water, each containing a few pieces of charcoal. Fix the bottles in an inclined position, so as to admit of the bunches hanging clear of the sides, and they may be so far apart as not to allow the bunches to touch each other. Keep the temperature of the room at about 45°, examining the bunches occasionally for decayed berries, which must be carefully removed. Prune the Vines, dressing the cuts with Thomson's styptic or patent knotting, and the house thoroughly cleansed. Admit air freely in favourable weather, seeking to give the Vines as long and complete rest as possible. Where the borders are not satisfactory lift the roots and relay them in fresh compost, and where the Vines have inside and outside borders the renovation may be accomplished without loss of crop by renewing the former one year and the latter the next.

KITCHEN GARDEN.

FORCING.—We shall not lift any more Rhubarb or Seakale roots for forcing, but the crowns will be covered with pots, old casks or boxes, and surrounded with hot manure. The produce will be ready in about three weeks after being covered, and while the roots will not be seriously impaired the fermenting material used in forcing will be in good condition for digging-in when the Potatoes are planted. Continue to lift Asparagus roots, and introduce them to a bottom heat of 70°, with the object of securing the produce in twelve or fifteen days. Kidney Beans sown in December are now 4 inches high, and ready for the largest pots. When short of pots or space we place four into an 8-inch or 9-inch pot. To still further economise space we have grown them in narrow boxes to suit some of the shelves, but they were not so prolific in the boxes as the pots. Ne Plus Ultra is our favourite forcing Kidney Bean. Where Green Mint or Tarragon are required lift a few roots, pot, and place them in any odd but warm corners to induce growth.

A DEFICIENCY OF MANURE.—Artificial manures answer many good purposes, but few if any of them can be used year after year as substitutes for farmyard manure, and it is this that is most valued for the great majority of vegetable crops. Market growers who have constantly to study the problem of how to make ends meet never grudge a lavish expenditure in manure, and private growers may remember this with advantage in dealing with the manure supply. At the same time cultivators may do much to increase their manurial resources by burning prunings and refuse, collecting all decayed vegetables and leaves, and securing manure from various sources to mix up with a general heap for use at cropping time. The present is the best time to form a heap of this kind, as it requires to lie for some time before being used, and if a quantity of soot can be mixed all through it the whole will be improved and cleared of insects—an important point in preparing a miscellaneous manure heap.

THE SALAD SUPPLY.—The frost and severe weather has almost destroyed the open air Lettuces and Endives. Those in frames are sound and good, but the deficiency of them that may soon occur should be met by an extra supply of Mustard and Cress, introducing more Chicory roots to the forcing quarters. With a supply of those, and stored Beet-root, no one need regret the absence of Lettuces in the early spring salads. Anyone with a glass house and a temperature of 60° may produce a constant supply of Mustard and Cress throughout the spring.

REVIVING OLD MUSHROOM BEDS.—Some of our beds that have been bearing since the end of October are now showing signs of being exhausted, but it is the heat that has declined and not the spawn that has failed. Sometimes when we have kept on our midwinter beds until the spring or early summer the natural warmth has induced them to begin bearing anew, and this induced us to revive fagging beds by supplying them with water heated to 90°, treading them the following day and beating the surface as in the first instance, and then covering them with a thick layer of dry hay or straw. As a rule the results of these simple operations are very gratifying.

PLANT HOUSES.

Loam.—If a good stock has not been wheeled under cover, no time should be lost in doing so, to have it in good condition for use when required. As opportunity offers it should be pulled to pieces and the worms removed. As this work proceeds it is a good plan to select the most fibrous portions, and store it for choice plants that need a compost of this nature. This is readily accomplished by the aid of an inch sieve. That which passes through should be again placed in a finer sieve, and the particles that pass through reserved for seeds, seedlings, cuttings, and small plants where a rough compost would prove unsuitable and out of place. It is surprising when good quantities of loam are prepared for use in this manner how quickly the work of potting, filling pans and boxes for seeds and cuttings can be carried on. It is a mistake to leave work of this nature until the busy season of the year.

Leaf Mould.—The quantity required for use during the spring months should also be under cover, ready for preparation during unfavourable weather. This undergoes a similar process to the loam, differing only in being passed through a sieve with a half-inch mesh. A heap of rough material may also be prepared by breaking it up with a

fork, removing the finest particles by the aid of a sieve, sticks also being carefully picked out. This rough heap, when cleaned, will be found useful for placing over the drainage of many plants, and incorporating with composts that are required as rough as possible. Our leaf mould is never stacked or used for potting purposes when too much decomposed. We prefer it while the fibre of the leaves is still perfectly fresh, which will be the case if the leaves have not laid more than 1 foot in depth, and are fully exposed.

Manure.—Where much potting has to be done at various seasons of the year it is necessary to wheel into a shed good heaps of manure in autumn and at the present time. The autumn supply consists of cow manure, from which the straw was shaken out, and horse droppings. The former, if moderately dry when stored, will rub easily through a half-inch sieve. It is useless to sift it if not dry enough, for if laid thickly together the labour of sifting would be wasted. If not sufficiently dry place it in boxes or flat bampers for a few days in the boiler house or other position to dry. Be careful that it is not baked, for this evil is as bad as sifting it when too wet. The horse droppings should be in good condition for passing through a sieve. The preparation of manure for potting is important; it cannot well be too finely divided for incorporating with other adhesive ingredients. If it is wet and adhesive it renders a compost with which it may be mixed unsuitable for use. Cow manure may be stored twelve months previous to being used when perfectly fresh. Our plan is to place it in an old shed and surround it with dry loam to soak up all the liquid that runs from it. This loam is equal to manure for many plants afterwards. As it is removed from the manure heap it is mixed with equal quantities of dry loam and a fresh supply placed round the heap of manure. No waste takes place by this method, and the loam that has been soaked with manure will be found invaluable for *Richardias*, *Cbrysanthemums*, and plants of a similar nature.

Artificial Manures.—The stock required for the year's supply should be ordered, so that it will be ready for use when required. Amongst these may be included half and quarter-inch bones with the fine left in, as well as a supply of meal. A box or barrel of soot should also be placed handy for use, and a few barrowfuls of wood ashes. Very few plants dislike the two latter, and either may be beneficially used in the majority of composts where loam, leaf mould, and manure are mainly employed.

Sand and Charcoal.—If the supply of the former is not equal to what will be required no time should be lost in getting in the necessary quantity. For mixing with composts it is much better dry than wet, especially early in the season when other ingredients have a tendency to be moist. Charcoal should be sorted and broken into suitable sizes.

Peat.—Sort this into three classes, that with the most fibre being reserved for Orchids, the hardest for Azaleas, Heaths, and other hard-wooded plants, while the lightest will do for Ferns. For the two latter it should simply be broken up with the hand, and Fern roots, pieces of wood, and strong roots of Heaths removed; while that required for Orchids should have all the particles of soil shook out of it, which will be useful for many small Ferns, Mosses, and other plants.

Pots and Crocks.—The former should all be washed ready for use where they are not washed up as they are emptied and stored away in their sizes. The crocks must be thoroughly washed; this is as important as using clean pots. The drainage of many plants is rendered untimely defective by the use of dirty crocks. When washed and dry sort and break them into various sizes ready for use, and place them separately. This is quickly done by the aid of sieves, except the largest or two largest sizes, and this can be selected during the process of breaking, and should be placed on one side first.

Labels and Stakes.—The first we have long since discontinued making, for they can now be purchased so cheaply. The necessary quantity should be ordered ready for use, and relabelling can be done as far as possible. It is a mistake to leave it until the different plants require potting, as is too frequently the case. Repoint stakes and tie them in sizes, it can then be seen what sizes and the quantity that will be needed. These if bought should be placed in early so that they can be pointed. Small stakes for a variety of purposes are generally in demand, and for this purpose large Bamboos are bought, cut into lengths, and split; the sharp edges are merely taken off with a knife, and the stakes pointed off at one end.

Boxes.—Some will decay, and to keep a good stock in condition for use a few should be made annually. We use common floor boards 6 inches wide. The ends and sides only want sawing into lengths. The bottoms are soon nailed on if the width is such that two or three boards without sawing will cover it. For three boards placed lengthways the boxes should be 19 inches wide, which will allow two half-inch spaces for drainage. If shallow boxes only are needed the boards may be sawed straight down the centre. Boxes last half as long again when thoroughly painted inside and out before they are used.

added to that we already possess, which will guide us better in the future in all things rural. "As a little spark sometimes kindleth a great fire," so will the neglect of doing a small thing give us much vexation, and often much labour and disappointment afterwards. Confining myself to the bee department, there were many instances where the honey harvest was nil. For similar reasons 1888 closed unfavourably for bees and the bee-keeper, and 1889 until the middle of May was even more so in many places; but wherever judicious management was adopted there was also a harvest of honey, greater in some places than in others, as is always the case, but in many instances there has not been an ounce of honey taken, although the bees were often situated short distances from successful apiaries—positive proof that there was something radically wrong in the management of the first named. If I were to write all the correspondence I get on bee matters it would sometimes fill up the greater part of the pages of this Journal, and would perhaps serve no good purpose, so care has been taken to write only that which experience has proved to be serviceable to bee-keepers in a profitable point of view.

One instance which will perhaps surprise some is worth recording. A number of straw hives which stood at the Heather in a northerly direction, and about fourteen miles from my own, rose in weight somewhere about 100 lbs., and the station master over that place told me his bees never did better. The geographical formation of the country had perhaps something to do with this. It lies in a broad valley between high hills north and south of it, so that the rain which deluged some parts of the country was almost absent there. One singular thing, for many miles round the rain fell in circles, and the places between these escaped. This was most frequent during August.

I do not for a moment think of advising bee-keepers to adopt straw hives, neither will I advise their owners to put them away and adopt frame ones. By simply pointing to results I should, for once at any rate, have the worst of it, and when everything is taken into consideration, including the teachings of those who advocate that extracted honey pays best because of the greater demand for it, much is in favour of the straw hive. I will not discuss the question further than that if the two kinds of hives had been standing near each other I have not the slightest doubt but that the owners of the straw hives would have seen the superiority of the wooden ones. Ocular demonstration, experiments and facts, are the best things to convince and reason on.

There has been very little if anything new in appliances for the apiary. Some old appliances have been termed new, and several we discovered and first gave to the world have been appropriated by and credited to others. The Editor of one paper credits someone with the discovery of carbolic acid for clearing bees from supers, as well as repeating the error that before "honey could be extracted by the Lanarkshire honey presser the combs had to be broken to a pulp!" Then in the December number, page 252, he says, "But there was more excuse for us twenty-three years ago than there is for the bee-keeper of to-day; we had no bee journals to guide us, and the sources of information now available were very limited indeed." An unmistakeable error. I grant there were not so many letters from bee-keepers published in those days, nor were so many novelties and peculiar ideas printed as now; but the more stable and sensible modes of management, which many are now returning back to, were taught, and queries answered, often, too, in a more rational manner than they are now in journals which have existed for a year or more—the *Philosophical Journal* and *Philosophical Transactions*, *Farmers' Magazine*, *Scottish Gardener*, and others; then in England there were the *Journal of Horticulture*, the *Cottage Gardener* (the leader in bee matters, which the back numbers show), the *Gardeners' Chronicle*, and the *English Mechanic*. Every one of these taught bee husbandry. The only interest the editors of any one had was the dissemination of bee husbandry, and it is to these publications that the bee-keepers of to-day are so much indebted.

THE BEE-KEEPER.

NOTES ON BEES.

A RETROSPECT.

IN looking back on the year that has closed upon us, and reflecting a little on the lessons it has given, more knowledge will be

SWARMING.

The causes of swarming and its prevention have long occupied the minds of continental bee-keepers, as well as those in the British Islands; but nothing has been brought forward that will in any way be serviceable to bee-keepers, nor prevent Nature taking its usual course. I have dealt with the subject largely, and have shown the causes of swarming, and the only preventive by the introduction of young and fertile queens at the proper time. "Felix" found fault with this teaching. I threw down the gauntlet, and along with many others waited patiently for his method of preventing swarming by "skilful management," but it has not been forthcoming, so young fertile queens, combined with ample room, must be looked upon as the only preventive until the fertile brain of "Felix" or others give other desirable and reliable information.

Another writer in a contemporary told us that the best thing to do was to keep the sort of bee that would not swarm! Novices would be apt to inquire what sort of bee is that, and where is it to be had; but experienced bee-keepers would only smile and exclaim, The bees that will not swarm will soon become extinct. It is the bees that swarm that give the large surplus of honey when a protracted fine season occurs.

SHALLOW FRAMES.

These have come more to the front during the past year, not only as being more suitable for bee-keeping generally, but as being suitable for disposing of honey in the comb, being better adapted for storing surplus honey than sections. The last-named original make are also giving way to the Lanarkshire ones with narrow bottom rail. As I have used these shallow frames between thirty and forty years, and the same hive without the ends on the bar for full forty years, it is pleasant to find that our ideas, plans, and modes of management are being largely adopted, although the journal the information is given in is not named or acknowledged. Judging from the past, it will not occupy much of the future until the system of management advocated so long in these pages becomes general.

BEGINNERS.

During the past six months I have been in correspondence with many beginners, asking for information. If health permit, I will, for their benefit, give some instructions in future numbers, which I trust will enable many to make a successful start, and secure a successful and profitable issue, and tend to make them more comfortable in the coming years, and that the first one, 1890, will be a happy and profitable one for all is the fervent wish of—A LANARKSHIRE BEE-KEEPER.

FAILURE IN THE INTRODUCTION OF CARNIOLIAN QUEENS.

"C. R.," after deposing a queen regnant, introduced a fertile Carniolian one, releasing her after being caged over the bees several days, but the bees deposed her. She had been slightly injured, having a depression on the thorax, which might tend to the bees' dislike for her. A second queen was treated similarly. "C. R." wishes to know the cause of his failure to introduce. It is more common than is generally supposed for hives to have more than one queen, and to introduce an alien one to such a hive is almost certain in every case to result in failure, as it also will be if eggs or larvae is in the hive. Sometimes queen cells may not be started by the presence of a caged queen, but often they are, and when this is the case the alien queen is sooner or later doomed to destruction. Hence the caution necessary to deprive the bees of the power of raising a successor from the eggs or larvae, and to cage the queen (when valuable) on every occasion at least forty-eight hours before releasing her.—A. L. B. K.

TRADE CATALOGUES RECEIVED.

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Cesspool Disinfectant (F. J.).—The free use of chloride of lime when the contents are being removed may perhaps answer your purpose. Sulphate of iron used at the rate of 3 or 4 per cent. to the volume of the liquid is also as good for rendering the use of sewage less disagreeable to the operators.

Galls on Apple Trees (Wimbledon).—The holes in the portion of young wood sent have not been caused by birds in search of insects, but by the puncture of one of the gall insects for egg deposition, and the ultimate emergence of the progeny which eat their way out. One of the galls was intact on the shoot, and you will perhaps find others by a close examination of the trees.

Ellandsia setacea (J. F. C.).—It is one of the small-growing species, and is easily managed if you can provide a suitable temperature for the plant. Employ a compost of peat and leaf soil, well draining the pot, and place the plant in a light position in a stove or any house where an average temperature of 60° can be maintained. Supply water freely at all times, but especially when the plant is growing.

Blisters on Holly Leaves (E. S.).—The appearance of the leaves is due to a fly puncturing and depositing eggs in them, from which maggots emerge and eat away the tissue in a similar way that maggots destroy the leaves of Celery. The Holly maggot has done great injury in many gardens, and in some its ravages have been checked by periodical syringings with a solution of softsoap and petroleum.

Soil for Apples (J. E. W.).—Excellent Apples are grown within fifteen miles of London. The best soil is that inclining to be strong, but not very adhesive; such as works freely in favourable weather, and in which Clover grows naturally, being usually suitable. It should be good to the depth of 2 feet and contain no stagnant water within 3 feet of the surface. We cannot usefully name precise localities, as we have no records of land for sale or lease. Information of this kind is obtainable from agents. Much, or most, good land within the radius indicated is necessarily costly, and we think too high in price to justify inexperienced persons investing in it for growing Apples alone for sale; at least, they will not do so on our recommendation.

Treatment of Allamanda Hendersoni (J. C.).—If the plant has been at rest during the past two months and kept in a temperature of 50° to 55° it may now be started. Prune closely back—similar to Vines grown on the spur system—if the plant has attained the desired size to cover the trellis on which it may be grown, or the portion of roof under which it is to be trained. If grown in pots the old ball should be reduced by half, and then soaked in tepid water. The same or a larger pot should be used, according to the space to be covered with the plant. The drainage of the pot should be liberal, and then covered with a good layer of decayed manure, the most suitable compost being rich fibry loam, one-seventh of manure, and coarse sand. Press the soil as firmly

as possible into the pots, and place the plant in a temperature of 65°, syringe twice daily, but give little or no water at the root until signs of growth are observed. If planted out remove as much of the old soil as possible, and employ fresh soil with a little more manure.

Artificial Manures (Pas).—We do not think that under the circumstances you would be justified in spending what to you must be a considerable sum of money on works of the nature indicated in your letter. They are all more or less costly, and contain a great deal of matter that could be of practically no service to you. It is not necessary to compound manures with the greatest nicety founded on analyses of different plants and crops, and practically useless doing so without also having elaborate analyses of the natural soils with which you have to deal. If you proceed with the experiments you appear to be making, test the effects of the manures on different crops, you will gain information that will be of more use to you than by spending more than you can afford in expensive books. The best and most successful gardeners of the day have become such by making the best use of their opportunities in the acquirement of knowledge from current literature and by thoughtful work in the garden. We are glad that your three years' reading of the *Journal of Horticulture* has proved so serviceable. If you bound the numbers with the indexes, and continue to do so, you will have information that will guide you safely in your occupation. We applaud your desire to gain knowledge, but your zeal must be tempered by prudence, and with due regard to the increasing demands of your family.

Selwood's Reinette Apple (T. A., Laleham).—The fruits you have sent are very fine, and a few tons of such would find a ready sale in London at the present time, as they equal in appearance the best of the Americans. You say the trees that produced them are old but healthy, and bear freely. Healthy they must be to produce such fruit, and the soil must be good for Apples. "The tradition that the grafts were obtained from abroad, and the variety only grown at Laleham," is, as regards the latter portion of it, inexact, though the Apple is seldom seen. Dr. Hogg has it in his collection, and refers to it as follows in the "Fruit Manual":—"The tree is a strong and healthy grower, and an abundant bearer. This is certainly a different variety from the Selwood's Reinette of the Horticultural Society's catalogue, which is described as being small, Pearmain-shaped, greenish yellow, and a dessert Apple. It is, however, identical with the Selwood's Reinette of Rogers, who, as we are informed in his "Fruit Cultivator," received it upwards of ninety years ago from Messrs. Hewitt & Co. of Brompton. The tree now in my possession I procured as a graft from the private garden of the late Mr. Lee of Hammersmith; and as it has proved to be the same as Roger's variety I am induced to think that it is correct, while that of the Horticultural Society is wrong. It received its name from a person of the name of Selwood, who was a nurseryman at the Queen's Elm, Little Chelsea, in the last century, where Selwood's Terrace now is."

Vegetables for Exhibition (Scotland).—A "Prizetaker" says, "Early sowing must be resorted to if extra fine samples of Celery, Leeks, and Onions are required for the August shows, and that in your case premature seeding was most probably due to the plants having received a severe check in the earlier stages of their growth. All three kinds may well be sown before the end of January thinly in pans and placed in gentle heat, a mild hotbed causing the quickest germination. Before the seedlings become drawn place the pans on a shelf near the glass, but still in heat, till all have formed leaves other than the seed leaves, the Onions to be gradually hardened, and eventually dibbled out where they are to grow as early in April as the state of the ground permits. It is the White Spanish type of Onions that are raised in this way, the produce being shown as spring sown, and is a long way in advance of any raised in the ordinary way. Tripoli Onions are the most liable to run to seed. They are usually autumn-sown in the open ground, and transplanted about 1 foot apart each way early in the following spring. They can also be had nearly or quite as fine by sowing in heat as just advised, and thus raised are less apt to "bolt" prematurely. Onions require to be grown on deeply dug freely manured ground, soot being also freely forked into the surface prior to planting. The ground ought to be in good working order, and made as firm as possible without causing it to bind together, surface hoeings and occasional supplies of liquid manure doing the rest. The treatment of Celery and Leeks may well be identical, and these require more labour to be spent on them than do Onions. First prick out the seedlings into other pans or boxes of light good soil, keep them in a light position still in gentle heat, and uniformly moist at the roots. Before the plants become overcrowded carefully lift the requisite number, or say two or three dozen of each, and place them singly in 6-inch pots, using fairly rich loam with plenty of charred soil and rubbish mixed with it. Keep them in heat till they have formed a few fresh roots, when all should be transferred to a greenhouse shelf or cool pit, being finally hardened before they are much root-bound. Transferring these somewhat pampered plants to cold trenches seriously checks growth, this being one of the causes of early running to seed. Instead of trenches prepare a site above ground for both Celery and Leeks. To the ordinary well manured garden soil add 6 inches of rich loamy compost, this being enclosed by stout stakes and 9-inch boards and lightly forked into the surface. Transfer the plants from the pots to this well prepared site, planting firmly, giving all good room, and sheltered if needed from cold winds or late frosts. Keep the plants well supplied with water and several liquid manure, and blanch by means of brown paper bandages in folds, or with paper and strips of canvas. The extra fine produce resulting from this treatment more than compensates for the trouble taken."

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*Tillington Rectory*).—A, Ringer; B, Robinson's Pippin; C, Sam Young; D, Bringewood. (*G. A. Mau*).—Beurré Rance.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*Subscriber*).—*Eucomis punctata*. (*W. G.*).—1, *Acacia dealbata*; 2, *Coccoloba platyclada*, also known as *Muehlenbeckia platyclada*; 3, *Acacia Ricana*. (*C. A. W.*).—1, *Fittonia argyroneura*; 2, *Urceolina aurea*; 3, *Dipladenia boliviensis*.

MILK OR BUTTER?

THAT dairy farming is profitable nobody attempts to deny, but profits differ in it as in other branches of farming very much

according to the quality of the produce and the manner of its disposal. Several of our personal friends have large herds of cows, yet most of them have a different way of management both of the cows and in the disposal of the milk. One sells the milk at the farm to a retail dealer who calls for it twice daily; another makes all the butter that can be had and rears a large quantity of pigs upon skim milk and home-grown corn; another sends most of the milk of his own cows direct from the farm to his customers' houses in "sealed" pint and quart bottles, and for butter a considerable quantity of milk is purchased from the neighbouring farmers. Large-mouthed glass bottles with screw stoppers are used, the stopper being secured by a neat adhesive label bearing the appropriate motto "Safe bind, safe find." This simple method effectually prevents the milk being tampered with, it tends to assure the consumer that he has a genuine article, and certainly answers the purpose of the producer whose dairy business became so extensive some time ago that he found it worth while to open a dairy shop in a town within a short drive of his farm. The one objection to the use of the glass bottles is the breakage, which involves an average annual loss of about £5.

Many other peculiar cases occur to us, such as the regular dispatch of all the milk by rail to London from long and short distances; the sale of the milk to a butter factory; the delivery of the milk to a retail dealer in a large town with a clear weekly settlement. In this case it is claimed that doubtful customers and bad debts are altogether avoided. Certainly the farmer is a thriving man, but then he turns the favourable situation of his farm to full account and does a profitable business in poultry, eggs, vegetables, and fruit. The farm is a small one, and the whole of the work is done by the farmer, with his wife, two sons, and a daughter, all grown up, and who thus worthily illustrate the proverbial bundle of sticks, and certainly cling together to good purpose. Thrift, industry, and a fair amount of intelligence and good sense have in this instance told so well that no complaints about hard times are heard; on the contrary, quiet expressions of satisfaction with the prices obtained for the whole of the farm produce are occasionally let fall. Poultry plays a worthy part here, about 100 hens being kept, and eggs recently have had a brisk sale at 2s. a dozen. It is simple nonsense to say that any considerable extension of poultry farming would bring down prices so much as to render it unprofitable. There is a wide margin to work upon, and the limits of profit will not soon, if ever, be reached.

A notable and highly satisfactory thing in the cases we have quoted, and many others known to us, is the admirable way in which all good farmers adapt themselves to the circumstances of their surroundings. For farmers generally the sale of milk is probably found preferable to butter making, both because of the saving of labour and the greater degree of certainty of a constant demand and brisk sale. Present rates are slightly in excess of 9d. per imperial gallon, or 1s. 8d. per barn gallon of 17 pints, less 1½d., or say an average of three fathings per imperial gallon for rail carriage, the cans being returned carriage free. Such landlords as Lord Hampden are doing much for the assistance of tenant farmers by the establishment of dairy factories, even if prices given for milk are placed upon the basis of small profits and quick returns. A steady inflow of ready money is a matter of vital importance to a struggling farmer. It is this want which so frequently bring young calves upon the market which should have been kept at the farm at almost any momentary sacrifice. Very seldom is it that really good cows are to be had by purchase, and every cow calf from a really good cow should be reared and kept for filling those inevitable vacancies in the herd which occur all too frequently.

Factories or no factories, butter making is profitable enough if only it is well done. We quite recently inspected a grass farm in the Croydon district, which strongly commended itself to our judgment as a sound investment for a tenant at the inclusive rent of £2 per acre, which was required by the landlord. It was excellent

sound pasture, in useful division, hard by a railway station, with a splendid neighbourhood for the sale of a first-class article. That is the point; only make first class butter of uniform quality, let your herd of cows be arranged upon a footing that will enable you to guarantee a regular supply of a given quantity, and though you may have a struggle to establish a reputation and obtain a connection, you are bound to do it, despite tempting importations from Brittany or any other country.

WORK ON THE HOME FARM.

The ravages of swine fever still continue in certain districts. A recent report states that during the last nine months 333 had been attacked, forty had been slaughtered, 244 had died, and forty-nine recovered. This was in South Lincolnshire, and the report tells further of eight flocks attacked by scab. The scab is in its way as infectious as swine fever, but it is easily got rid of by dipping the sheep in Cooper's dressing, and no particular harm is done if the sheep have attention at once. Swine fever is always more or less fatal, and farmers should always be on their guard against infection. More than this, there should be an end of slovenly practice in the management of swine. We recently built a range of piggeries with concrete floors, tiled roofs, with doors to the stys as well as the courts. There ought to be no difficulty in keeping such buildings perfectly clean, yet when we called to see them after the tenant had only used them for a week we found the usual horrible accumulations of filth. Our own piggeries are old ones, having boarded walls and partitions with tiled roofs, and floors all faced with Portland cement. We only use litter for bedding in the stys, none being used in the courts, which are swept out every day, and the litter is changed once every week. All the woodwork is limewashed, and they are thus kept quite sufficiently sweet and clean. At the present time we have a considerable number of porkers in course of preparation for the London markets, and care is taken not to suffer them to be crowded, and to take a little extra care as to cleanliness. Some of these porkers are reserved for sows, and they are fed as highly as the others, to bring them into breeding as early as possible. We recently purchased a lot of pigs that are capital examples of the value of judicious cross-breeding. Essex pigs are notoriously coarse, long-bodied animals, but the pigs we purchased were the result of a cross between an Essex sow and Berkshire boar, the result being compact animals, with many of the Berkshire's best points sufficiently prominent to render them altogether superior to the ordinary Essex pig.

OUR LETTER BOX.

Cow for a Small Farm (J. M.).—The most profitable sort of cow for a small farm is a cross-bred animal of tolerably large frame, naturally inclined to a lusty condition, with a large udder and rich milk. Such cows are to be found at most good dairy farms, and you ought to be able to obtain one in your own neighbourhood. But you must be prepared to pay a special price for the privilege of selection, as no one will part with a really good cow if he can help it. The average price of a cow in full milk now is £25, and for £4 or £5 more you ought to be able to obtain what you require. But you must be cautious and avoid mere cattle dealers, whose habit is to try and put a false gloss upon every animal they have to sell. Do not be tempted by cows offered for sale at fairs or markets, but rather go to a large dairy farm or some breeder of repute, and if possible select a young cow that has recently had its second calf, and is consequently at its best. Notes on manures will appear in an early issue.

REMARKS.

- 5th.—Wet till 1 P.M.; showery afternoon; fair evening and night.
 6th.—Dull and showery morning; cloudy afternoon; wet evening.
 7th.—Sunshine throughout.
 8th.—Cloudy morning; fine afternoon, some sunshine; showers in the evening; bright night.
 9th.—Fine, with sunshine in the morning; wet afternoon and evening; solar halo at 11.30 A.M.
 10th.—Cloudless morning; high wind and a little cloud in the afternoon.
 11th.—Overcast, with frequent spots of rain in the morning; drizzle in the afternoon and evening.
 A mild and showery week, but with two perfect days. Temperature more than 15° higher than that of the preceding week, and nearly 10° above the average.—G. J. SYMONS.

THE remarks by Mr. Wright on the emigration of gardeners to the United States of America and the Dominion of Canada in a recent issue of the *Journal of Horticulture* (December 19th, 1889) were peculiarly interesting to me. Who is to blame for our overstocked market? The manufacturer! True, gardeners often take apprentices with nothing in view except the "almighty dollar," yet they are not wholly to blame, as they frequently have raw material put into their hands by proprietors of gardens, out of which they are expected to manufacture an article for which there is no present or prospective demand. Every individual of ordinary mental capacity and the needful practical application may readily become an expert, but as gardens are not so easily manufactured as the gardeners it follows that there is a glut, and the gardener as well as the farmer must, if there is to be national increase, seek fresh fields. With the artisan it is different. Skilled labour is fully employed because the field enlarges by the production of a cheapened and superior article, but cultivators must seek fresh pastures; in fact, the cultivator is the pioneer of civilisation—the maker of trade and commerce.

Emigration is, indeed, a necessity to the British farmer and gardener. It is practically useless, however, sending a gardener abroad who has failed through lack of energy at home, for in emigrating to the United States of America it must be borne in mind that we have, so far as the States on the Atlantic seaboard and the great northern and central cities or seats of trade and commerce are concerned, to compete with a people fully equal to our own in all essential qualities, and with the advantage of being more adaptable, more inventive, more eager to get on, and less under the influence of routine and prejudice. If the experience of one who has passed six years in the United States and Canada mean anything, it is that considerable physical force and mental energy are necessary for enduring the strain put upon them in what proved "a struggle for existence."

The experience I shall endeavour to give was obtained by an individual assumed to possess ample energy and competence as a gardener in good establishments in England—viz., apprenticed to a good all-round gardener or orchidist in the environs of Liverpool, helper in a good all-round establishment in the neighbourhood of Darlington, foreman in a marquis's garden, also with three M.P.s, two of them baronets, ultimately becoming gardener to a baronet, from whose service came in due course a release. Then came the inevitable waiting for a market. A market not being obtainable in England, it was resolved to seek one in the United States of America, and, following the same lines as Mr. Wright traversed with his medical friend, I shall keep back nothing except the name (which I place in the hands of the Editor as an evidence of good faith) of our gardener friend, who furnished the particulars under circumstances that will appear later on. Our "brother of the spade" left England 10th January, 1884, in the s.s. *Polynesian*, Liverpool to Philadelphia, nine days to Portland, weather rough, head winds, overcast, Portland to Boston on to Stonington by rail, from the latter to New York by water, and then on to Philadelphia by rail, these journeys occupying two and a half days, or eleven and a half days from Liverpool to Philadelphia. Work was obtained the second day after arrival at Philadelphia with a florist, in the houses under a foreman at twelve dollars per month and

board, with promise of advance to fifteen dollars in summer. He was quartered with coloured men, which was objected to, with the result that our friend was told to leave, and he did so after six weeks' employ. He secured work again readily with an Irish florist, jobbing and trimming up plots, twenty cents per hour, no rations, and although only promised a few days or a "leg up," had five weeks' employment. Failing to obtain heed for the credentials taken out—as the Yankee makes a practice of proving his man as the Englishman does his horse—a move inland was made, a few days planting Tobacco in Connecticut, three miles from Hartford, supplying the needful for the journey to Rhode Island. Three miles from Providence work was got at hoeing Yellow (Indian) Corn at two dollars per day, where a stay was made over hay, Wheat, and Oat harvest, the employer being a dairyman and an Englishman. From there a journey was made northward, entering Maine the 13th August, finding Wheat, Barley, and Oats harvested.

He there engaged with a farmer, owner of a 100 acre farm, at twelve dollars per month with board and rations. Had to learn milking, the stock being eight cows, twenty-nine bullocks, thirty-five sheep, three hogs, five hundred fowls, and six hundred pigeons. Four horses were kept. The farmer worked, the wife worked, milking the eight cows before the new hand learned to milk, and when he did, found a "mother" in the farmer's wife. No female servant was kept, "I was the whole and sole dependant and help—a veritable man Friday." The first work there was cleaning Yellow Corn, Potatoes, Turnips, Beans (Haricot or Pea Beans), Tomatoes, Squash and Pumpkins (Vegetable Marrows), Melons, Cucumbers, Carrots, &c., housing as matured. Then came the getting in of the Maize crop, which does not do well, and is not much grown, but is a paying crop for forage, dried and stored as hay. Sweet Corn is much grown, paying well, being sold to factories for canning. Apple harvest came in due course, there being three acres of full grown trees, all choice varieties, Baldwin and Cornish Gilliflower being the two best winter varieties for dessert, Baldwin of course being equally good as a culinary sort. New York Pippin, large, red streaked, culinary or dessert, good, fall (autumn); Ten-ounce Pippin, large, culinary or dessert, red streaked, beautiful; Seek no Further, red and yellow, good to eat and cook, keeping till March; Northern Spy, Northern Greening, and Golden Russet were fine, the latter very prolific, and keeping sound until May; Early Harvest, gathered before ripe to retain juiciness and flavour: and Red Astrachan, large, very fine, gathered or used off the tree are the best early Apples. The ground under and between the trees was cropped with Rye, allowed to ripen, and valuable for its straw for thatching.

The trees were standards 24 feet apart; pruned in winter, well thinning the heads with a saw. The Apples as gathered were placed in barrels at a cost of twenty-two cents each, and when filled with fruit these were worth one dollar each, the sender paying carriage to the port. Five barrels were considered a good day's work for a man, the fruit being shaken down, left in the orchard to sweat but kept dry. One tree will yield from three to four barrels, all picked fruit, refuse being kept for cider, hogs, and cows. "Borers" infest the trees, to keep down which the stems were white or lime washed, or the insects killed by a red hot iron thrust into the holes in spring. All insects that seek to lay their eggs are kept from ascending by a broad ring of cotton wool, about 5 feet from the ground, with a tin cover to keep it dry and effective. Pears are not much grown, as they do not succeed, nor do Peaches and Grapes. Cherries do well, as Black Heart and May Duke, they with Apple trees being planted in hedgerows, taking a similar place there to what timber trees do in England. Timber, or rather lumber, is grown on land that is not suited for tillage. Plum trees do not succeed.

In Maine a stay was made of one and a half year, as during the preceding winter a desire came, often and strong, upon our friend to follow "his own business;" therefore he left the "best

master and kindest-hearted man ever servant had served," and a thorough-bred Yankee. Winters were occupied in chopping wood, taking manure to fields, and attending to stock. The winter season extended to four months, very cold, often at zero, and occasionally 39° below zero. The summer season was eight months, high temperature, 75° to 80° and often 90° in the shade. Winter wages, twelve dollars; summer, fifteen, board and rations, which if not a great wage was amply met by the "comfort and consideration shown and felt." The farmer, it ought to be noted, had been a schoolmaster, saved some money, bought a farm, taking to rural life for employment and delight; but the Yankee must do or die—i.e., make money or lose it; therefore the farm must pay, working like a horse all the summer, and idle in the winter only—i.e., read and contrive all day long, and enjoy summer's givings, clearing in many "a season more dollars than were given for the land." "Tons of books" were this Maine farmer's only solace.—UTILITARIAN.

(To be continued.)

THE notes that appeared in this paper of December 19th bear forcibly on several conversations we have lately had with gardeners in various positions on the subject of gardeners out of situations. We do not intend to touch on emigration, but wish to say a few words on how it would be possible to better our position in this country. We are told there are fewer gardeners out of employment in England than men of any other trade or profession. However true or false this may be we know not, but about one thing there can be no mistake, there are numbers of gardeners out of situations at all seasons, and the temporary employment offered to them by nurserymen may account for their not being enumerated amongst the unemployed.

A gardener may leave his situation for a variety of reasons, and in the event of no suitable situation presenting itself the only course left open to him is to go into the nursery, there to wait for the chance that does not always come as soon as he anticipated. What does a gardener gain by working for a nurseryman for weeks or months, and in some cases for over a year, for a wage less than some of the common labourers? He gains nothing for himself, and does a great deal of injury to the permanent staff in a nursery. We do not say that a gardener is doing wrong because if he cannot get a whole loaf he takes a half, far from that. We honour the man who can take up the pick or the pade and bravely face whatever comes in his way, but we do say gardeners are wrong in not endeavouring to do something for themselves against the evil day when a man finds himself out of a situation, and where is the gardener that has not this uncomfortable presentment? A hundred things might happen over which he has no control, and which might be the means of his having to leave his place.

There is no class of men in a better position than gardeners are for placing themselves out of the reach of this difficulty. That is one of the greatest drawbacks a gardener has to contend with in the present day. They are not, as a rule, so highly paid that they can afford to spend money on advertising, which we imagine is one of, if not the very best, modes of gaining situations. Nor can they be very long out of a situation without doing something for the means of existence. This being the case it must be apparent that some little help at this time would be the greatest benefit a man could wish for. Now, were gardeners to form a body, call it by some name, and pay a certain sum of money for twelve months, at the end of that time a man leaving or wishing to change his situation would communicate with the society, when they would at once begin to advertise for him, and so place him into a situation sooner and more suitable to his ability than he could ever hope for through a nurseryman, and in the event of his not immediately obtaining a suitable appointment some sort of help might be devised for him. Were a society of this sort once started there is no bounds to what it might include for the united good of the

gardener; but this we will leave to wiser heads than ours, and should this suggestion meet with the approval or otherwise of anyone who might read it, we should be glad to hear their views on the subject.—B, *Cheshire*.

A FEW GOOD VEGETABLES.

ALL who are wise will not readily discard old and well proven favourites in favour of the unknown, the superior merits of which have yet to be discovered, but if certain varieties have given every satisfaction in the past, some of them have been eclipsed by later additions to the list. This being so, there is every reason why a few novelties, or any strongly recommended by those who have already given them a fair trial, should be tried alongside older varieties, and if the latter are surpassed, then ought they to go down before their superiors. But I annually try a few novelties, and when I come across a good thing I not only grow it again and more extensively, but also give others the benefit of my experience. The latter I hold to be the proper thing to do, and I believe comments upon superior varieties of vegetables are always thoroughly appreciated by numerous readers of the *Journal of Horticulture*.

Some of the leading catalogues first enumerate Peas, and to a few varieties of these I will first allude. I find that William Hurst is equal to Chelsea Gem, both being excellent dwarf early varieties, suitable alike for frames and sheltered borders. There is nothing very new among the taller growing early varieties, nor any startling novelty among the second early forms. None that I have tried equals Telephone for succeeding William I., and Criterion is still my favourite for succeeding Telephone. I was never much in love with Duke of Albany, as it invariably suffers badly from mildew here, but I can speak highly of Autocrat as a good main crop and late variety. Goldfinder is a good form of Ne Plus Ultra, and the same may be said of Magnum Bonum, the last named being scarcely so tall growing as the type. Both succeed admirably in our strong soil, and fewer rows of the ever-popular Ne Plus Ultra are sown accordingly. Those who prefer or must have varieties of medium height only, will find Stratagem still unsurpassed for second early and main crops, and Carter's Anticipation is well worthy of a trial. Webb's Wordsley Wonder is very serviceable, and one of the best for small gardens. It is a second early variety, and has long been a favourite with me. Very good also are Royal Jubilee and Satisfaction, both sent out recently by Messrs. Sutton & Sons. Latest of all and Sturdy are excellent for the latest sowings, and on the whole those who cannot afford room or stakes for tall-growing Peas have no cause for complaint anent the scarcity of suitable and profitable varieties.

Of Broad Beans the most profitable early variety is found in Veitch's Improved Longpod, this being a great cropper, the lower pods, all of which are of a good length, quite touching the ground. No improvement can hardly be effected on this. Beck's Dwarf Green Gem, though quite an old form, is still not so much grown as it deserves to be. It is dwarf, branching, and early, the pods being small and filled with small green beans, or just such as suit the cooks. If exhibition pods are needed, then Leviathan ought to be grown. The broad podded later varieties are also being increased in length. Veitch's (Exeter) Improved Broad Windsor is a notable instance of this, and other firms have improved forms. There is nothing very new that is valuable in the way of Kidney Beans, Canadian Wonder and Negro Long-pod still being the best for main crop, while for forcing and the earliest sowings in the open there is none to equal Ne Plus Ultra. Those who want extra long-podded Runner Beans can get them by sowing either Veitch's Mammoth Scarlet, Carter's Jubilee, Girtford Giant, Mammoth White, or Ne Plus Ultra. I give the preference to the last-named as being the least coarse.

There is nothing fresh to chronicle concerning Beet, the best we have being the old Dell's Crimson. Last season Veitch's Improved Black was very superior, but the roots of this we are now using are too coarse. Dobbie's New Purple, as shown at the Chiswick Conference, gained plenty of admirers, the colour of the by no means coarse roots pleasing all alike. We still prefer Read's Hearting Borecole, the old Asparagus Kale being, however, more hardy, and is the best for a very late supply of succulent greens. The value of Veitch's Self-protecting Autumn Broccoli is now too well known for the variety to need any eulogy from me, and Michaelmas White is also early and good. Snow's Superb White affords a fairly close succession to the first named, and of this the Sandringham (Carter's) is an admirable selection. The Cape varieties are far too delicate, and the Penzance Early White is a wretched failure, an ordinarily severe frost destroying the plants. It cannot be kept in a dwarf or semi-hardy state. Spring White, Cooling's Matchless, and Leamington form an admirable succession, while Safeguard

(Sutton's) is a valuable addition to the list of late varieties, this hearting in just in advance of the distinct and good Veitch's Model. The best latest varieties I find are Ledsham's Latest of All and Sutton's Late Queen. Brussels Sprout Ne Plus Ultra, synonym Northaw Prize, is my favourite strain, this being of moderately strong even growth, a sure cropper, the sprouts being of medium size, firm, and mild in flavour. Exhibition grows rather stronger, and this also is a profitable stock.

Ellam's Early, Matchless, Paris Market, and Early Etampes were all good and are well adapted for close planting in private gardens, as also is Wheeler's Imperial. Chou de Burghley or Cabbage Broccoli ought to be grown for the midwinter supplies. We have abundance of it at the present time from seed; being the first week in May the majority of the hearts are sufficiently compact. Savoy Cabbage ranks among the most reliable winter vegetables we have, only an extra severe frost much injuring them. Tom Thumb is of neat growth, early, and good in quality, while the Early Dwarf Elm is very good in every way. Gilbert's Universal is also of fairly neat growth, while the quality is exceptionally good. Dwarf Green Curled and Drumhead afford a good succession, but they are somewhat coarse. The list of Cauliflowers is still being added to, one of the latest novelties, Sutton's Magnum Bonum, being a decided advance. It is suitable for second early and main crops, is of dwarf yet fairly vigorous habit, and the produce of superior quality. The Early Forcing is quite a little gem, Erfurt Mammoth forms a good succession, while for the autumn nothing can well surpass Veitch's Autumn Giant.

Last season we tried several varieties of Carrots, especial regard being paid to the invaluable Horn or Stump-rooted sorts. Parisian Forcing (Vilmorin), a small round smooth-rooted form of French Forcing, is superior to the latter for frame work. Guerande was found to closely resemble Early Gem and Model, and this form under any name is well worthy of a trial. It forms shorter and thicker roots than Nantes Horn. For the latter I have a great partiality, and if a single variety only was sown that would be the one. Matchless and New Intermediate are apparently synonymous and much superior to the old James' Intermediate, and Carter's Scarlet Perfection is also a superior form of Intermediate, the quality of the last named being very good. Celery Veitch's Early White is the best white variety I have yet tried, this early in the season almost equalling Major Clarke's Red for solidity, crispness, and nutty flavour. Veitch's Early Rose is another distinct and good novelty, Major Clarke's Red and Standard Bearer completing the selection. The Parisian Celeriacs are decidedly superior to the form generally offered and grown in this country. The new Apple-shaped and Large Smooth Prague are of very compact growth and form good sized bulbs of the best quality. I ought perhaps to warn the inexperienced against the White Plume and Golden Yellow Self-branching Celeriacs, as they are erroneously termed; unless moulded up they are uneatable, and under any circumstances inferior.

Leek Ayton Castle Giant is good enough for the non-exhibitor, but if extra fine stems are required The Lyon may well be grown. Nor are enormous Onions of much value for home use, and for this purpose we are well content with Main Crop, Giant Zittau, and either James' Keeping or Brown Globe for spring-sowing, while for autumn sowing The Queen, White Naples, Giant White Tripoli, and Giant Rocca are satisfactory. Turnip Early Milan is by far the quickest to bulb, but keeps badly. Early Snowball and the French Early Paris Market, white oblong variety, which keeps extremely well, are good for most crops. Veitch's Red Globe is fine for autumn and winter use, and none equals Chirk Castle Black Stone for hardness and quality. Potatoes and Tomatoes I must pass.

Cabbage Lettuces Early Paris Market and Perfect Gem are our favourites, White Paris Cos and Black-seeded Bath Cos being also largely grown. We tried a considerable number of varieties, but those just named, all things considered, are the pick of the lot. The Louviers Endive (Vilmorin) is both distinct and good, in fact the best for the earliest crops, Picpus Green Curled also being good. The White Batavian or Lettuce-leaved Endive is superior as regards perfect blanching, crispness, and mildness of flavour, being almost equal to good Cabbage Lettuce; but it is not nearly so hardy as the Improved Round-leaved Batavian. The latter is simply invaluable for late autumn and winter use. Endives are rightly receiving attention from raisers of novelties, and in the Victoria Improved Round we have a great improvement on the ordinary form; this, besides giving much finer leaves, also stands well. Much the same remarks apply to the monstrous Viroflay and the new Long Standing, and one or more of these varieties ought to quite supersede the old forms.—W. IGGULDEN.

[We have received several letters on the subject, the insertion of which would tend to bewilder rather than instruct, and the

above careful estimate of the leading crops is sufficient at present for practical purposes.]

NOTES ON HARDY FLOWERS IN KIRKCUDBRIGHTSHIRE.

WITH the new year flowers are beginning to peep out from their winter quarters. The common Snowdrops have been in flower since January 10th, and have, as they so often do, again proved untrue to their popular name of "Fair Maids of February," and shown that the old couplet,

"The Snowdrop in purest white arraie
First rears her head on Candlemas daie,"

like so many others, must be accepted with some reservation. Many clumps are now in flower on slopes and ridges of rockwork or on the level ground. *Galanthus Elwesii* is also in flower.

The little Winter Aconite has also expanded its bright golden flowers. Common and cheap as this little *Eranthis hyemalis* is, it is yet indispensable in the early spring garden. The first Daffodil of the year opened its flower on 13th January. It is *Narcissus minimus*, and has surprised me by its earliness, having far preceded all the others in my garden. The others, including *N. pallidus præcox* and its early varieties, will be some time before they open. This plant of *N. minimus* formed one of a small lot of imported bulbs purchased in 1888, and has not been out of the ground since October that year, so that lifting and drying cannot be ascribed as the reason of its early flowering.

Colchicum crociflorum is in flower, but an envious or admiring gastropod has thought that its delicate white flowers with blackish purple stripes would form a delicious meal, and has not only "marked," but "inwardly digested" to such good or evil purpose that our flowers are a pitiable sight.

Some of the early species of *Crocus* are only awaiting some gleams of sunshine to enable them to expand their brilliant blooms. Such an early season as this is not a good one for these early Crocuses. They get too far advanced before they get much sun, and cannot stand the drenching rains we are experiencing. Those I have ready to flower are *C. Imperati*, *C. Sieberi*, *C. Aucheri*, *C. minimus*, and *C. biflorus*, the Scotch *Crocus*. They are mostly very beautiful, and although I admire the large named Dutch Crocuses, of which I grow some twenty varieties, the above and the other species in my garden give far more pleasure, coming as they do at various times. *C. Imperati* is one of the earliest and most desirable species. When in bud the flowers are a soft fawn pencilled with black, and when open a bright purple. We have a number of *Polyanthuses* and *Primroses* in flower, and some of the late *Chrysanthemums* still give a few blooms.—S. ARNOTT.

IMPROVED BLACKBERRIES.

MR. D. BROWN asks for information as to where he can obtain any improved varieties of the common Bramble. If his object is to obtain an abundance of good sized, juicy, well flavoured fruit, I recommend him to plant the Parsley-leaved Bramble (*Rubus fruticosus laciniatus*). Low-lying cold situations should be avoided for the plants, and the natural habit of the Blackberry in its wild state should be studied. I have during several years seen the Parsley, or Cut-leaved variety, grown in gardens, especially where a loamy soil existed, elevated situations, and plenty of room, with a tall trellis for the shoots to be trained to, and capital crops of large juicy fruit were obtained.

Questions have been asked as to its being an American variety or a native of Britain. *Rubus fruticosus*, the common Blackberry, is a plant widely distributed throughout Europe. The variety *laciniatus* is not mentioned in Hooker's "British Flora," or in the London "Catalogue of British Plants." In Loudon's "Arboretum et Fruticetum Britannicum," published 1838, it is stated in reference to *laciniatus*, "Where it was first found is unknown, but it is in all probability only a variety of the common Bramble." In Nicholson's "Dictionary of Gardening," published in 1887, no native country is given. I have often wondered why this excellent Blackberry has not had more attention from practical gardeners than it has, and I think that there are amongst the American kinds some which may under proper treatment be worthy of notice, but I must say I have very little knowledge of their value, as I am not in a position to test them.—RUBUS.

TROPÆOLUM JARRATTI.

THIS is stronger in growth and has larger flowers than *T. tricolorum*, the flowers of both being scarlet, yellow, and black. Both are very neat twining plants, charming for covering trellises, which may be flat (in which form they form admirable floral screens) or globes; the leafless top of a Larch or Spruce tree when well covered has a fine effect.

The tubers require to be potted so soon as they begin growing, which is usually in August. They should have pots proportionate to the size

of the bulbs. Large bulbs require 8 or 9-inch pots, whilst a 7-inch pot will accommodate a medium-sized bulb. I employ 9-inch pots, and have three bulbs in a pot, having a Spruce top for training the shoots to. The bulbs are placed triangularly in the pot, leaving a clear space in the centre for the introduction of the stem of the Spruce, which, clear of the pot, will be $2\frac{1}{2}$ to 3 feet high, and half the height in diameter at the base, running up to a point so as to form a pyramid. I prefer this form because the plants take up less room.

Drainage is given to the extent of one-fourth the depth of the pot, covering it about an inch deep with the rough of the compost, which consists of equal parts of light turfy loam, leaf soil, and sandy peat, and a sixth part of silver sand. Fill the pots to within 2 inches of the rim, place the bulbs with the growing side upwards upon a little silver sand, and surround with the same material. Cover about an inch deep, the potting being done moderately firm. It is well for the soil to be in a moist state, but not wet, when employed for potting, so that necessity for watering may not arise until growth takes place.

The plants may be placed in any light airy cool house, and as soon as the shoots are long enough training should commence. The object should be to cover the trellis of whatever form it may be equally in every part with flowering shoots. Upon this depends in a great measure the beauty of the specimen, to secure which very frequent regulation of the shoots is required, not leaving them until they become entangled, it being difficult to disentangle them without much injury resulting.

Water should be given rather sparingly at first, avoiding at all times making the soil sodden, and yet the plants must not be allowed to suffer by want of water. If water be given when the soil is dry—a thorough supply—all will be well, making it liberal when the plants are in full leafage and advancing for flowering. When the flowering is past the leaves will shortly after turn yellow, when water should be gradually withheld, discontinuing it when they are all in that state. The bulbs, after the stems are withered, should be taken up and kept in a cool dry place until potting time again arrives.

They succeed admirably in a winter temperature from fire heat of 40° to 45° . Aphides sometimes attack them. It is best destroyed by fumigation with tobacco, but it is necessary that the foliage of the plants be dry and an overdose be not given, or the foliage is liable to suffer.—G.

BRITISH APPLE CULTURE.

AT pages 38, 39, Mr. Wm. Thomson of Clovenforis makes a few pertinent remarks, but he fails to point out the resources some countries have over Britain in making barrels. It is quite true we could turn out barrels so far as the making is concerned as cheap as any nation, but we lack the forests of suitable timber, and are therefore much handicapped in that respect, while every day timber is rising in price. I fail to see the advantage barrels have over square packages. The latter can be made to "nest" better than barrels, and can be returned as empties in this way more cheaply and easier than if sent singly. About thirty-seven years ago I contracted with a fruit merchant to make nesting boxes for all kinds of hardy fruit, so that a return load of something could be brought from town, a thing not easily done when the empties occupied the same space as full packages.

Apples are being imported from Normandy, packed in shallow square cases, and judging from the appearance of the fruit this seems a more desirable way than packing in barrels. These Apples have a peculiar flavour, entirely their own, and are sold at 3d. and 4d. per pound this season.

I feel certain that timber packages will have to be more economically dealt with in the future than making kindling wood of. Willows might occupy many acres of what is at present uncropped ground, and the making of hampers would give employment to many unable to perform other work.

Lord Suffield Apple has never found favour with me as a cooking Apple, being, in my estimation, much inferior to the old Keswick Codlin; nor are any of the newer sorts equal to a variety known locally as "Perston" or Pearston. Size in many cases is the only recommendation possessed by Apples.—W. T., *Blantyre*.

A FEW NOTES FROM AMERICA.

MANY of the older generation of horticulturists will remember Mr. J. W. Laurence and the Farnham Castle Orchids in Bishop Sumner's time, Mr. Laurence having been gardener there for about twenty years. Soon after the death of the late Bishop Sumner, and the disposal of the Orchids, Mr. Laurence and his family emigrated to America, and started a business at Pittsburg, but a very advantageous offer being made to him to remove to Harrisburg, Pa, he did so. In a letter I have just received from him he writes, "Our business keeps on increasing, and the locality is healthy, only that age is telling upon me. Still I am to enjoy myself in the greenhouses amongst the Primulas, Cyclamens, &c. We make a speciality of both, and send young plants of our Primulas all over the States in the fall, and have a fine stock in 5-inch pots for Harrisburg. We go in now for raising our own seed successfully. Our Cyclamens are the finest strain in the United States, and some of our plants could not be covered by a half-bushel measure."

"We have had a whole year of bad weather. Last winter it was slushy, and our horse was not roughed once, and the sleigh was not once used. The summer has been wet, but we are here on high ground fortunately; for Harrisburg had its share of the floods in every street

The Susquehanna rose 27 feet. Our Tomato crop was good but rather late. Potatoes have decayed badly, Grapes also, but we saved much of our crop by spraying with the Bordeaux mixture. In fact the weather has been as bad as ever I saw it in England, and it has been raining now (November 21st) for a week. Apples are a great failure this season, so our vinegar crop is short. Strong winds blow all the flowers off the Apple trees. We had a cyclone or two this summer, which blew down a lot of houses, and made things lively; but the town puts up more, and goes ahead as usual. All the streets have the electric light, and steam heat is laid on to the houses in the same way as water or gas."—W. D.

MEDLARS.

I DO not think the value of Medlars is generally known, and I cannot understand why they are not more cultivated. I do not advise anyone to grow them so extensively as Apples and Pears, but from one to half a dozen trees might advantageously be grown in every garden. The trees are naturally of ornamental habit, so that they are well adapted for planting in pleasure grounds. They produce a luxuriant mass of leaves, a great show of pinkish white flowers. They rarely fail to fruit, as a rule, heavily, and neither insect nor bird, or any kind of pest, ever attempts to injure the crop. The fruit may be allowed to hang on the tree until November. It is hard and apparently green at that time, and they have to be drawn from the tree when they are spread out in a layer three or four deep in the fruit room or similar place. There they remain, and early in December some of them begin to soften. As soon as they are in that condition they are ready for use, and they will be found a very agreeable addition to the dessert.

They remain in use for about two months, and when so many of them are ripe at once that they cannot be used as dessert they should be preserved. Medlar jelly is a great delicacy, and for this purpose alone the fruit merits most extensive cultivation. Indeed I question if there is a finer jelly made than that from Medlars, as it is of a beautiful colour, and the flavour gives general satisfaction. There are four varieties of the Medlar. The Dutch is large but not superior in flavour; the Monstrous is still more so in both respects. The Royal is medium sized and good, but what is known as the Nottingham is the smallest and best flavoured. The latter is the one I prefer. As to culture they are as easily grown as a Gooseberry or Currant. They will succeed in any ordinary soil or locality, and the best time to plant is during winter when the leaves are off. They are offered in dwarf pyramid and standard forms, and the latter form the most handsome trees.—J. MUIR.

CYPRIPEDIUM SEDENI.

THIS Orchid is rarely out of flower when grown in the warmest house throughout the year. It increases rapidly in a warm moist structure when given liberal root room, in fact it is an almost continuous grower. Such plants are seldom removed from the house in which they are grown except on special occasions, but when in flower a prominent position is accorded them. Less water is given during the winter; but the soil is never allowed to become thoroughly dry, and no attempt is made to force rest upon the plant.

CYPRIPEDIUM SPICERIANUM.

Certainly charming when in flower, and one of our plants annually produces two flowers from the one stem. It is slightly different both in the foliage and colouring of the flower than the other plants. It is a good grower when given careful treatment and a warm moist temperature, but it requires care during the winter, or its foliage will become spotted. Abundance of water is necessary throughout the summer, and it must have material about its roots that does not decay quickly. Plants potted in loam are liable to have the leaves spotted; the soil becomes too close and often too wet during the winter. Our plants do well in charcoal, crocks, and peat fibre, with living sphagnum on the surface only. The roots cling firmly to the sides of the pot and to portions of crock that are used in the compost. During the worst weeks of the year the plant should not be watered over the foliage. This we carefully avoid, but give to the roots a moderately liberal supply. No harm results, because the compost is open, and the water quickly drains away. Cold water must not be used; it is certain to end in the foliage being spotted. It should be a few degrees higher than the temperature of the house.

ODONTOGLOSSUM ROSSI MAJUS.

Where choice flowers are in demand throughout the winter months, and those of Orchids are appreciated, large quantities of this useful Orchid should be grown. It is particularly cheap, and a good number of pans with from six to eight strong flowering pseudo-bulbs can be made up for a very small outlay. It is questionable if any Orchid yields a better return in flowers for the cost and attention than this. It grows with us like a weed in 5-inch pans that are about 2 inches deep. One good crock is placed at the base, a few smaller ones over it, and the plants are potted in a compost of peat fibre, small pieces of charcoal, with a little moss on the surface after the plants commence to grow. We elevate them little above the rim of the pan; they are gradually sloped from the centre towards the rim, and the base of the outer pseudo-bulbs is level with this.

We purchase early in the year as soon as we know of a consignment that has arrived in good condition, which is nearly always the case. If we buy large pieces, which we seldom do now, they are broken up. It is a mistake to place them on the surface in the often crowded condition in which the pseudo-bulbs are when they arrive. With us these pieces have never done so well as those that are broken up. After the plants arrive our first work is to pull them to pieces, remove all dead and decaying matter from amongst them, wash them thoroughly in tepid water, and then spread them out on a board for a week or ten days, sometimes longer, even until they display signs of moving. During the interval between arrival and placing them in pans they are occasionally dewed over with the syringe, in fact whenever the board becomes dry. There is no better place than a vinery just started for them. After they are placed in pans they are suspended about 15 inches from the glass in the Odontoglossum house, or any other structure where the temperature and atmosphere are similar. They are only lightly dewed with the syringe until active growth and root activity has commenced. The chief object at first is not to overwater them. Strong flowering bulbs are then made the first season. We give less water to this Orchid during the winter than to other Odontoglossums. On the other hand, the material about the roots is never allowed to become really dry. We were led to this practice some years ago through the first imported plants we potted. They grew away as freely and made as fine pseudo-bulbs the first season as well established plants. The drying they had undergone in transit had done them no harm. We have kept them drier during the resting period than most people do, and the results have been highly satisfactory. The puny growth and sickly condition in which this plant is often seen we believe to be mainly due to their having too much water during the winter.—ORCHID GROWER.

A NOVEL DENDROBIUM.

The first meeting of the Royal Horticultural Society's Orchid Committee for 1890, which took place on January 14th in the Drill

FIG. 9.—DENDROBIUM NOBILE BURFORD VAR.

Hall at Westminster, was an exceedingly interesting one, and augured well for the coming season. Several beautiful novelties were exhibited, and prominent amongst these were the hybrid Dendrobiums from the Society's President, Sir Trevor Lawrence. These have already been described, and we may have occasion to refer to them again, but there is one which calls for special notice now. This was exhibited and certificated under the cumbrous

title of *Dendrobium nobile* Burford variety, for which something much more concise and elegant might have been readily substituted. This is a particularly interesting Orchid for several reasons, but that which will chiefly concern cultivators is that it is decidedly attractive, and while regarded as a curiosity it will, if its

FIG. 10.—DENDROBIUM NOBILE COOKSONIANUM.

characters remain constant, become a favourite addition to the varieties of the most useful *Dendrobium* grown.

The lip, petals, and dorsal sepal are similar to those of any other good variety of *D. nobile*, but in the two lower sepals we find a peculiar character, the rich crimson colouring of the lip seems to have been extended to their lower halves in broad bold bars. A peculiar appearance is thus imparted to the flower, of which an idea can be formed from the representation of a flower in fig. 9. It will be seen at once that it has some resemblance to the now well known "three-lipped" *D. nobile* Cooksonianum, but in that the deep colouring is confined to the lip and the petals, these three organs thus assuming a very similar character. This peculiarity can be more readily understood than the transference of colour to the sepals without affecting the petals, but the occurrence of this variety has given rise to the impression that it is possible to obtain one with the lip colouring in *all* the sepals and petals, and we should at once have a regularity that would be approaching the florists' ideal. Whether such a form would be an acquisition from an orchidist's point of view is doubtful. Except as a curiosity I do not think it would. It appears to me that one of the great charms of Orchid flowers is in the absence of rigid formality and exact symmetry.

That *D. nobile* Cooksonianum and the Burford variety under consideration are good there can be no question—indeed, a plant of the former shown at the same meeting awakened general admiration, and though I have seen that variety many times I have never been so impressed with its distinctive beauty. The illustration here (fig. 10) reproduced, for comparison with the Burford variety, was prepared some time ago from a good flower, and in describing it I stated an opinion to which I still adhere—that having been named Cooksonianum in error it should have received its proper designation, Heathfieldianum. However, the substituted title has been so generally recognised that it would be difficult now, and perhaps inexpedient, to attempt to supersede it.

The whole subject of transferring the lip colour into the other divisions of the flower, which also occasionally assume the lip form, has been discussed scientifically by the late Professor Reichenbach as *Trilabellia*, particularly in the paper he contributed to the Orchid Conference in 1885. In that he referred to instances occurring in *Oncidium Papilio*, *Laelia elegans*, *Oncidium prae-textum* *Leeanum*, and *Phaenopsis Stuartiana* *Lendyana*, but some of these were much more marked than in the *Dendrobiums*, the lips being reproduced in triplicate exact in form and colour. Some such examples I have seen, but they always seem more like monstrosities, and certainly do not possess the beauty of *D. Cooksonianum*. There is one other *Dendrobium nobile* variety, named *Tollianum*, which has the colouring in the petals, but more confined to the margins, the lips are turned the reverse way (upwards) from their normal position, at least this was the case with a plant

recently exhibited at the Drill Hall. The sepals and petals also more closely surround the lip, being less spreading, and consequently the colouring is not well seen.—L. CASTLE.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.

ELECTION OF OFFICERS AND PENSIONERS.

LAST week we published the statement of accounts of this valuable Institution, and on the date of its appearance officers were elected for the ensuing year, and fifteen candidates placed on the pension list, six without ballot in accordance with the rules, and nine by the election of members. The officers chosen were H. J. Veitch, Esq., re-elected Treasurer, and Mr. R. Cutler, Secretary. Lord Revelstoke and C. Czarnikow, Esq., were elected Vice-Presidents, in the place of the late Sir M. Peto, Bart., and the late Mr. R. Marnock. Messrs. H. Turner and G. Wythes were elected, and Messrs. J. H. Weston, J. Webber, W. T. Baker and S. Osborne re-elected members of Committee.

The six candidates placed on the pension list as stated were Emily Friend, Mark Hebblethwaite, Eden Georgina Murray, John Skene, John Trotter and John Wainwright. The candidates elected by votes were James Baillie, 3241; Sophia Burt, 2369; Mary Ann Milroy, 1890; Elizabeth Parker, 1568; Sarah Brush, 1543; Robert Cox, 1537; George W. Young, 1493; Maria Milley, 1430, and James Robinson, 1213.

THE DINNER.

In the evening about seventy members and friends of the Institution celebrated the election by a social dinner where many similar gatherings have been held in previous years—namely, Simpson's Hotel, in the Strand. Mr. Edmund Yates presided, and all who were present will admit that he did so most happily. Mr. Yates is one of the literary celebrities of London—a man of the "World" in more respects than one—who can make a much better speech with a cigar in his mouth, and keep it (or both) going, than many persons could with all they desired to say written out before them. Loyal toasts, however, came before cigars, and were proposed befittingly and accepted joyously.

The CHAIRMAN then proposed "Success to the Gardeners' Royal Benevolent Institution." He said he had been supplied with figures bewildering and statistics appalling, showing the good that had been done, and of which his hearers probably knew better than he did; but he would say, and he said it gladly, that the Institution was the most prosperous of the many with which he was pleased to be connected. He had been interested in horticulture from childhood, commencing with growing Mustard and Cress, and he hoped the pursuit would afford him and all pleasure till all were sown. He thought no profession in the world was so natural, so wholesome, so helpful, and so suggestive of what was pure and good, and so stimulating to the finer feelings of man, as that of gardening. The speaker gave examples of this from poets, and concluded by expressing his delight in engaging in horticulture, particularly as he found it that night, for it tempered labour with refreshment, dealt hospitably with friends, and he hoped he should be among them again when prosperity was drunk to the Gardeners' Royal Benevolent Institution.

Mr. JOHN LEE in rising to respond met, as he always does as the venerable father of the charity, with an ovation, and many were the expressions of pleasure on seeing him look so hale and well. After an allusion to his acquaintance with the Yates family, many years ago in Hammersmith, he referred to the election of pensioners, observing that out of the list of twenty-five candidates only some half dozen had been supporters of the Institution, and the fact of so many having to wait still longer for election proved the necessity for more subscribers. He earnestly hoped that gardeners as a body would see the advisability of associating themselves with it early in life.

Mr. H. J. VEITCH, rising in response to the toast of his health as President of the next anniversary dinner in June, was loudly cheered. He said, though no one rejoiced more than he did with the candidates who were elected, he would have been glad if more of them had been subscribers. He was particularly pleased to see that Mrs. Milroy had been placed on the pension list. Her husband joined the Institution many years ago, at a time when he had no reason to think either he or his would be likely to require its assistance. He joined for the good of others, subscribed for twelve years, then was called away. His widow might have long ago sought benefit from the fund, but by great endeavour supported herself for twenty years before making application for election. This example of self-denial he thought worth mention, and he was delighted to see Mrs. Milroy now on the list. Referring to the position that he accepted, almost with fear and trembling, to preside at the next anniversary, he could not but remember that he was succeeding a munificent friend of the Institution (Mr. Leopold de Rothschild), whose presence at the dinner brought an increase to the fund of nearly £3000. Still, someone must succeed him, and he, after much consideration, consented to do so. Having done this it was his intention to do his very best for the charity, and called on all to do their best in helping him to increase its means for doing good. With the co-operation of many friends, though he could not hope to approach the results of his great predecessor, he must confess he should like to accomplish something that his successor would not find it easy to beat, especially when he announced, and he knew the announcement would be warmly

received, that the gentleman who had consented to follow him and preside next year was no other than the talented Chairman of the evening, Mr. Edmund Yates. (Loud cheers).

Mr. GEORGE PAUL, in acknowledging the toast of the nursery trade (Mr. Moss having responded for the seed trade) made a strong appeal to all engaged in the industry of horticulture to support a representative as President of the year, his friend Mr. Veitch. He trusted that nurserymen and seedsmen all over the kingdom, also gardeners, would heartily co-operate, and he was confident if his hopes were realised the year would be one of the best financially, and the dinner one of the most successful that had been experienced in the history of the institution. (Cheers.)

Mr. PARKINSON proposed the President, Vice-Presidents, and Committee, Mr. Herbert Adams and Mr. G. Monro responding. Somebody proposed the "Guests," for whom Sir John Monckton replied, and Mr. Sherwood introduced what he thought must be the toast of the evening—"Our Chairman."

MR. YATES, in response thereto, remarked that he had been told—but he feared if they took a good look at him the statement would not be believed—that he was with them thirty years ago; but it would be true if he lived, as he hoped, to take the chair as arranged in 1891, for it was in 1861 that he first sat down to a dinner of the Institution. He remembered that, because it was the first time he had addressed a public assembly. But, oh! the dinners he had attended since; the speeches he had made, the nonsense he had talked. That was not his fault: it was the fault of the Gardeners' Benevolent Institution, and his services (whatever they might be worth) would always be at its disposal. (Cheers.) He was now going to perform an act they were told was good—forgive an enemy. He had been tormented by a man all the evening who would not let him sit still, but he was in other respects such a good old frisky young fellow, such a true friend to and ardent worker for the Institution he had made to flourish, that he would ask them to join heartily in drinking his health, for his name was Cutler: and again, with emphasis—CUTLER. Then came a volume of sound, and "So say all of us."

Mr. CUTLER, in responding, said he thought they were doing a little too much. He had, however, been elected to the position he held for the forty-ninth time that day, and hoped he should live to be chosen once more. He could work better for gardeners than do his own gardening. He had tried to grow his own things, and put up a "sort of a house." He planted Melons, and they went on fine for a time till they had fruit as large as eggs, but hang him if they would get any bigger. He was in a quandary, when a friend came to the rescue and said, "What a fool you must be to bother with these things with so many gardening friends." Well, he (Mr. Cutler) thought there was something in that, so he trusted his friends to supply him with garden stuff; and they had not failed him; and he would not fail so long as he had strength to do the best he could as Secretary for the Gardeners' Royal Benevolent Institution. (Cheers.)

Miss Mary Belval, with her accomplished assistants, enlivened the proceedings by songs and glees delightfully rendered at intervals during the evening, which was of a very enjoyable character throughout.

MANNERS AND CUSTOMS—A CATALOGUE COMMENTARY.

(Continued from page 43.)

Madame Lacharme (Lacharme, 1872).—Of fair growth and foliage, with most characteristic habit. The shoots require to be severely thinned, and then they must be looked over from top to bottom several times during the growing season, as it is such a free bloomer that every wood bud will break and must be stopped before the top flower bud begins to swell. Very liable to mildew, and absolutely spoilt by any rain after the bud begins to show colour. Even a heavy dew will sometimes soil the blooms. These are of a pure white, and for years this Rose was the best H.P. of its colour, a row of it in full bloom looking most charming just as the dusk of a July evening comes on. Water appears to wash the colour off the petals and leave them transparent, for they are of the most delicate texture, and will show the ravages of thrips sooner perhaps than any, and as these are sure to come in some places in hot dry weather, and wet is even more fatal, *Madame Lacharme* has often a bad time of it. The shape is good, globular, with the centre well filled, but the size is not generally more than medium. It will come again well in the autumn if it should be particularly dry and fine, but as the best white H.P. it has been completely eclipsed by *Merveille de Lyon*, and must put up with the qualification "best under glass."

Madame Noman (Guillot, 1867).—Another pure white H.P., but a weak bad grower with small foliage. The blooms also are quite small, but of exquisite form and the purest colour. This Rose and *Boule de*

Neige are much better shaped than Madame Lacharme or Merveille de Lyon, but are so very small in comparison as to be completely out of it.

Madame Prosper Laugier (Verdier, 1875).—Of good strong stiff growth, with very distinct appearance and habit. Well spoken of as a useful Rose, but I could never get it to do at all with me, and have had to discard it long since.

Madame Victor Verdier (Verdier, 1863).—A very strong grower, with fine foliage beautifully coloured in the spring. Not liable to mildew, but rather worried by rain. A well known crimson Rose, which by no means comes up to its reputation with me. It is free flowering, and forms plenty of buds in the autumn, but I cannot honestly say that they come too much, nor are they as large as they ought to be in proportion to the growth. I have been gradually discarding it during the last three years, but I should gather from the general opinion that it does better with other cultivators.

Magna Charta (W. Paul, 1876).—Exceedingly strong growth, with large foliage; not very liable to mildew or much injured by rain. With me a coarse Rose, very large, double, and showy; rough on maidens, and generally much wanting in refinement. Fairly free blooming considering its size, and sweet scented, but a very bad autumnal. Hardy, and of strong constitution.

Maréchal Vaillant (Jamain, 1861), syn., *Avocat Duvivier*.—Of good growth and foliage. A fairly free flowering, hardy, good ordinary common Rose, with no particular manners or merit.

Marguerite de Roman (Schwartz, 1882).—Of Victor Verdier race, with all the special manners and customs of the family. Lighter than Marie Finger, but smaller, and not so good.

Marguerite de St. Amand (Jamain, 1864).—Of fine thorny growth, with good foliage, very green in the spring. Not liable to mildew or to be injured by rain. The blooms almost always come well, of a delightfully fresh pink colour, and of regular but rather open shape, well filled in the centre. A capital Rose, one of the best of its colour, free blooming, and a good autumnal; of large size, and good lasting quality. I am informed that it is an unfortunate custom of this Rose to be particularly palatable to rabbits, who will search out and attack it first among any number of Roses.

Marie Baumann (Baumann, 1863).—This is a Rose of great reputation. The growth as a cutback cannot be called more than fair, and the foliage is not large. The wood is moreover weak and pliable, and unable to support a heavy bloom, which therefore hangs over with its face to the ground. This habit undoubtedly detracts from the appearance of the flowers while on the plant, and they must be supported for show. Fragrant, not much injured by rain, but very liable to mildew. "Always good in all seasons," a very high quality claimed for this Rose, is perhaps rather too strong an expression. It was very good last year, much better than the year before, for all Roses are more or less affected by the weather and the season; still it is a wonderful Rose to "come good," and in this respect is perhaps more reliable than any other. Free blooming and a good autumnal, fair in petal, good in centre, of typical globular form, often very like Alfred Colomb (not only in shape, but also in colour), of large size, lovely smooth outline, and fair lasting qualities. It must be well cultivated, and will not do in poor soil or on the Manetti stock; but though it cannot be called a hardy sort of strong constitution, it has been for many years, and appears likely to continue to be, one of the most popular of Exhibition Roses.

Marie Cointet (Guillot, 1872).—One of the "weak robust" sort, like Madame Charles Wood in growth. Not liable to mildew, but suffering from rain. The blooms do not always come well, but when they do the petals are thick and good, the shape well imbricated, and the centre nicely filled. No use as a free bloomer or autumnal. Very good in lasting qualities, but (keeping the worst to the last) decidedly deficient in size.

Marie Finger (Guillot, 1872).—Better, I think, than Mdle. Eugénie Verdier, which is held to be a synonym. Of Victor Verdier race, with all the manners and customs of the family, but decidedly one of the best of them. The growth is often marked moderate, but with me it is as good as that of any of the tribe. A most beautiful colour, often nearer what I call "salmon" than any other Rose. A row in good bloom will often draw your lady visitors, who are more attracted by colour from even your brightest crimson. Of large size, but not of very good lasting qualities, the centre being rather weak, and the form soon lost. Very free blooming and an excellent autumnal.

Marie Rady (Fontaine, 1865), syn., *Comtesse de Choiseul* and Mrs. Jowitt, is much like it. Capital strong growth and foliage, not very liable to mildew, but utterly destroyed by any rain, even when quite in the bud state. Requires dry hot weather, and then most brilliant and superb; a striking contrast to the ugly, dull, brown rotting balls which are seen in a showery time. The blooms are large and particularly heavy, and any poet who speaks of being "pelted with Roses" as an æsthetical luxury may, I think, be convinced of error if he will allow me access to my "Rady's" in a damp season. A free bloomer, but does not shine as an autumnal; comes well as a rule if the weather is right with stout petals, very full centre, globular imbricated shape, brilliant red colour, and capital lasting qualities, but has a tendency to coarseness on maiden plants. A good hardy sort, likely to be in demand after a dry season, and to be neglected after a wet one.

Marie Verdier (Verdier, 1877).—Of short growth as a cutback, but

fairly healthy and strong, with good foliage, very green in the spring. Not very liable to mildew, and opens tolerably, but loses colour in rain. The blooms come generally well formed, with something of the cupped shape, the centre being well filled. Its strong points are the size, thickness, and smoothness of the petals; in these particulars it is hard to be surpassed. Fairly free blooming, but cannot be called a good autumnal; of large size, lasting in shape, but not in colour. A very good show Rose, particularly noticeable for the length and smoothness of its petals.

Mary Bennett (Bennett, 1884).—Fine shape, thick petals, good colour, and a good laster, but quite a bad grower. I cannot get it to do at all.

Marquise de Castellane (Pernet, 1869).—Of robust habit; sometimes a very strong grower, with thick long thorny shoots and fine foliage, but rather capricious in this matter and difficult to please. I see one professional of note quotes the growth as "moderate." My own impression is that it used to grow stronger than it does now. My plants, all treated exactly alike, are most uneven, some being very weak and some very strong. I have known it do well in light soil, but am not prepared to say that it likes it. At any rate, it will not be of any use if it does not make strong growth. The blooms frequently come unevenly shaped, but they very large and most effective when good. Not liable to mildew or much injured by rain, early, free flowering if it does well. Not very good in lasting qualities, but a capital autumnal, coming of good size quite late in the season.

Maurice Bernardin.—See Ferdinand de Lesseps.

Merveille de Lyon (Pernet, 1882).—Of Baroness Rothschild race, in all manners and customs resembling it in every particular. The finest white H.P. Rose by a long way; inclined to come with a slight pink shade in the autumn, but a grand Rose of the largest size. The blooms open quickly and are rather weak in the centre; they must be cut quite small for exhibition. This race has a splendid hardy constitution. I have no blanks in my cutback rows of this Rose and the Baroness. The plants are all alike and even; none die or are ever "sick or sorry." A capital autumnal, and a great acquisition altogether.

Miss Hassard (Turner, 1875).—Of strong thorny growth. Hardy, fairly free blooming, and a pretty pink colour, but the shape is weak and loose. May perhaps be considered worthy of a place, as being one of the earliest.

Monsieur Boncenne.—See Baron de Bonstetten.

Monsieur Noman (Guillot, 1866).—The growth of this Rose is puzzling. One catalogue gives it as robust; the majority call it "free," which may mean anything, but can generally be interpreted as "not bad enough to be classed moderate," and the National Rose Society's catalogue gives it as "very moderate," this being the only H.P. thus stigmatised. I remember that I was much surprised when I first saw this, as I was then trying to grow Roses in light gravelly soil, and it is no exaggeration to say that, in a good sized collection, Monsieur Noman was one of my best growers, but the blooms were not first-class. Now that I grow it in better soil it is decidedly weak in growth, but the flowers are much better. The characteristic wood is very enticing to prune to, if you do not know "its tricks and its manners;" for the base of every shoot swarms with great strong red buds, looking as if the plant was going to grow like fun next year; but the experienced pruner will leave very few indeed of these buds, and allow but few shoots to grow. It would be better, perhaps, to bud it annually, following the recommendation of the National Rose Society's catalogue—"best from maiden plants." Not liable to mildew, but absolutely spoiled by rain, which will cause the blooms to gum and rot in the early stages, and stain the petals when they are expanded. It pays well for a cap or protection of some sort in showery weather. Fine in petal and shape, clear in colour and large in size; a very free bloomer, but not of much use as an autumnal.—W. R. RAILLEM.

(To be continued.)

DRESSING ROSE BLOOMS.

IN thanking "D. Deal" for his words of admonition to myself, and for the complimentary terms in which he writes of dressing Rose blooms provided it is successfully done, will you allow me space for a rejoinder?

First, as to my supposed departure from the usual course pursued by members of committee. In writing to you upon a subject which was discussed at the annual general meeting of the National Rose Society, I recorded opinions intended to have been made personally had I attended the meeting. So that unless I should have been out of order, because a member of Committee, in taking part in the public consideration of the question at the meeting—not a Committee meeting, remember, but a meeting of subscribers, the proceedings of which have been reported in your paper—I can hardly be precluded from stating those opinions in a letter to the *Journal of Horticulture*. If I have thus trespassed, and I plead ignorance to the fact that the motion was put forward by the Committee, I humbly apologise to all affected thereby, especially to my friend, "D. Deal," to whom I appear to owe many thanks for his forbearance in letting this point pass.

Now as to the main point. Permit me to explain why I concluded that the decision in the case of Roses dressed "out of character" was "to be left to some other authority than that of judges." It was because the clause which deals with overdressed Roses is added to rules which have been and may again be enforced by that "other authority."

For it should be borne in mind that only in the case of duplicates (see rule 9) shall the judges' decision be absolute; rules 7 and 8, to which the dressing clause is appended, may be carried into effect by that "other authority." I thank "D. Deal," for his interpretation that dressing shall be dealt with solely by the judges.

But if this is so, is not the clause out of place in its present position, and altogether superfluous? Is there an exhibitor who intends when he dresses his Roses to do more than (I give the words of "D. Deal," in his description of the art) "to display their charms to the best perfection, and such dressing the rules of the Society acknowledge to be fair?" Exhibitors, like other people, make mistakes at times and overdress their blooms, as I know to my cost. It may happen that someone, especially a beginner in his eagerness to be first, overdoes it—the Rose is dressed "out of character," it is a blot in the stand, it is a bad bloom. Now, what is the penalty for thus spoiling the bloom? Nothing more, says "D. Deal," than that which is accorded to a bad bloom—the disqualification of the Rose, not the stand, by the usual method of judging. Surely it did not require a special clause on dressing to be added to the rules which refer to the disqualification of the exhibitor—not the Rose—for gumming, wiring, and the like! The judge comes to a bad bloom in a stand; he does not stop to consider whether it is the result of rain, overshadowing, bruising on the journey, or overdressing; he sees the bloom is a bad one, and deals with it accordingly. I myself, with other judges, have come across blooms spoilt most probably from overdressing, but we did not require this ambiguous clause to enable us to deal with the blooms according to their deserts.

I ought not to omit to acknowledge the very flattering terms in which Mr. W. R. Railem speaks of my poor attempts at dressing Rose blooms. My letter has not been unsuccessful if only for having elicited from such an excellent authority, exhibitor, and judge, his admirably expressed opinion that "dressing is often beneficial and desirable, and sometimes necessary."—JOSEPH H. PEMBERTON.

NOTES ON ROSES.

CLIMBING Niphetos fully bears out the raisers' description as to the growth it makes; its flowering qualities we have not been able to test, but hope next season to speak favourably on that point. Another good new Rose is Souvenir de Mme. Joseph Metral; its bright red blooms are full, of good shape, and is a fine addition to the climbing Roses. If as good under glass as in the open it will rival Reine Marie Henriette. Among Teas Sappho seems to be a good grower. We have not flowered it yet. If up to the raiser's description it is certainly worth having. Mme. Scipion Cochet is first class, with large solid blooms that remain fresh a long time. Luciole is also good, and quite distinct in colour. Mme. A. Etienne is likely to prove useful, and probably better forced gently. Elizabeth de Grammont resembles a dwarf Gloire, sweet, of good constitution, with ample foliage. Château des Bergères is an improved Isabella Sprunt, and most suitable in the bud state for cutting. Duchesse de Bragance I cannot speak very highly of. It is a weak grower, but may improve with age. Mme. Bois is a good addition in the Victor Verdier style. Mme. Désir was very good, a free dwarf variety, but likely to be influenced by the seasons in the matter of opening. Mme. J. Desbois, Mme. Treve Marie (distinct colour), Dr. A. Joly, Comte de Paris, Queen of Autumn, Silver Queen, and Mme. H. Pereire are all good.—S.

SPECIAL PRIZES FOR TEA AND MOSS ROSES.

The following prizes have been offered in addition to those already provided for Roses at the meeting of the Royal Horticultural Society on June 24th:—Class V., for amateurs only, six varieties, Tea and Noisette Roses, three blooms of each, £2, £1, and 10s.; first and second prizes by Mr. Frank Cant, third by Mr. Prince. Class VI., for nurserymen only, twenty-four varieties, Teas and Noisettes, distinct, £2 10s., £1 10s., and £1; offered by Dr. Hogg, F.R.H.S., F.L.S., &c. Class VII., twelve varieties, Teas and Noisettes, distinct, three blooms of each, £2 10s., £1 10s., and £1; offered by W. H. Fowler, Esq. Class VIII., open, twelve varieties of Moss Roses in bunches, £1 10s., and £1; offered by Messrs. George Bunyard & Co. and Messrs. Cooling. Class IX., open, a basket of Tea and Noisette Roses, in tripod wicker baskets, as at National Rose Society's Shows, Rose foliage only to be used; offered by Messrs. Paul & Son.

DESTROYING PARASITIC FUNGI.

I MUST apologise to Mr. G. Steel for not replying to his inquiries before (see page 560 last vol.), but as Mr. Steel coupled Mr. Tonks' name with mine for the information he required I thought it prudent to give Mr. Tonks the opportunity of replying first. As Mr. Tonks has responded so ably I will now deal with the matter. In the first place I am asked by Mr. Steel if I can recommend anything that will destroy the Hollyhock fungus. My answer to this is in the affirmative, for I am quite confident the composition I have been experimenting with for the last ten years will destroy any species of fungus either indoors or out wherever it can be applied to it. In proof of this I may say I have battled successfully against fungus on the Gloxinia, Begonias, Roses (outdoors and in), fruit trees (outdoors and in), the Melon canker, and severe attacks of mildew on Grape Vines, which have baffled many a good gardener. I now come to that part of Mr. Steel's letter where he quotes me—"I was now convinced the enemy was a fungus of some description, and treated the trees accordingly." This was after I had tried all other remedies suggested, and had I followed my own dictates I should not have had half the trouble and anxiety,

as I should have treated the trees for a fungus from the first, therefore it was not the remedy I had to seek for.

Mr. Steel asks me for the name of the composition I used. The original, as used by Bell, was called mildew composition. I may state I was placed in the above gentleman's nursery at an early age, and was called upon to assist the manager to make up a stock of this same composition. When I became older I made many experiments on various kinds of fungoid growths, but without any apparent good results, not even exterminating severe cases of mildew. I therefore came to the conclusion the concoction was wrong (yet it was made in every respect the same as Bell's). I knew the composition contained two substances which were valuable antidotes against the fungi, but other ingredients were added which neutralised their power. By dispensing with these and adding other chemicals I have brought it to its present state of perfection. I shall be pleased to send a few bottles to two or three gardeners or nurserymen, on their paying railway expenses, for experimental purposes and report thereon, and should it prove as effective as with me I shall be most happy to bring it out for the benefit of my brother gardeners.

In reference to Mr. Tonks' remarks I should like to ask him if ever he took in hand to eradicate mildew on Grape Vines with the compositions he names, and with what result, as I have frequently made use of them both (the sulphur and lime especially), but I cannot recommend them only in a very mild case, for I find it only partially destroys it, as the mildew soon reappears. In conclusion, I may say if Mr. Steel should accept my offer he should add about a wineglassful of the composition to one gallon of warm soft water, and syringe the plants two or three times a day.—ALFRED BISHOP, *Westley Hall Gardens, Bury St. Edmunds.*

EVENTS OF THE WEEK.—To-day (Thursday) Messrs. W. Bush and Son will resume the sale of the late David Ward, Esq.'s, Orchids at Mount View, Sheffield; the Royal Society has a meeting to-day at 4.30 P.M. The Quekett Microscopical Club meet on Friday, January 24th, at 8 P.M.; and the Royal Botanic Society on Saturday, January 25th, at 3.45 P.M. On Monday, January 27th, the National Chrysanthemum Society's Annual General Meeting will be held in Anderson's Hotel, Fleet Street, at 7 P.M. The Society of Arts has a meeting on Wednesday, January 29th, at 8 P.M.

— THE WEATHER in the metropolitan district has again been extremely variable, but several bright days have been experienced that are most welcome at this time of year, especially to those engaged in early forcing. Snowdrops, Winter Aconites, and Primroses are flowering in many gardens, and though the wind has been keen at night, little frost has been registered. Rain has fallen somewhat heavily on two or three days and nights, while Saturday night was very stormy.

— THE WEATHER IN THE NORTH.—The week has been extremely disagreeable, high winds and rains prevailing throughout. The 15th was an exception, being fine. Some of the nights have been tempestuous. There has been no frost. At 9 P.M. on the 16th the thermometer stood at 40°. Cold sleety showers with high gusty wind fell all throughout yesterday, and this morning (20th) the hills all round are white, and the low grounds covered with slushy snow.—B. D.

— DAFFODIL MEDALS.—It is announced in the schedule of the Royal Horticultural Society that Messrs. Barr & Son have placed at the disposal of the Council three silver medals, to be awarded at the great Daffodil Conference, April 15th, to the following exhibits:—Open to amateurs only.—1, Small silver medal for the best and most distinct twenty-five varieties of Daffodils, three flowers of each. The three great groups, Magni coronatæ, Medii coronatæ, and Parvi coronatæ must be represented. No Polyanthus Narcissi. 2, Large silver medal for the best and most distinct fifty varieties of Daffodils, three flowers of each, to include representatives from the Trumpet, Incomparabilis, Barri, Leedsii, Backhousei, Nelsoni, Burbidgei, Poeticus, &c., sections, but no Polyanthus Narcissi. Open to all comers.—Large silver medal for the largest, finest, most varied and distinct collection of Daffodils, irrespective of the number of flowers. No Polyanthus Narcissi.

— THE DEATH OF MR. C. R. M. TALBOT, the "Father of the House of Commons," has been recorded in all the newspapers. His handsome residence, Margam, and its delightful surroundings, have been described in this Journal, and instructive matter on various

subjects has been derived from the gardens and communicated to our pages by Mr. J. Muir. When visiting Margam we were pleased to hear so much that was good about Mr. and Miss Talbot. Just and generous to tenants, and considerate and kind to servants, they were beloved by all. Miss Talbot, we believe, is the inheritor of the immense wealth of her father, and her pleasure in gardening being great, there is reason to hope that Mr. Muir will not be restricted in his work through the great change referred to.

— A TELEGRAM to a London daily paper announces the DEATH of Mr. Peter Henderson, the well-known florist and seedsman of New York, which took place on January 18th of influenza. "He was born at Pathhead, near Edinburgh, in 1823, and came to America at the age of nineteen, and built up the immense business which has made him famous throughout the country."

— ROYAL HORTICULTURAL SOCIETY.—The following gentlemen are recommended for retirement from the Council for the ensuing year:—Messrs. J. R. Bourne, W. Coleman, and A. H. Smee; and the names of Fellows recommended to fill the vacancies are Messrs. E. A. Hambro, N. N. Sherwood, and Martin R. Smith. The officers recommended by the Council are Sir Trevor Lawrence, Bart., President; D. Morris, M.A., F.L.S., Treasurer; Rev. W. Wilks, M.A., Secretary; and Messrs. George Deal, W. Richards, and Harry Turner, Auditors. The annual meeting will be held on February 11th.

— WARE AND DISTRICT HORTICULTURAL IMPROVEMENT SOCIETY.—A successful meeting of this Society was held on the 13th inst., the Rev. A. E. W. Lofts in the chair. Some excellent Primulas, Roman Hyacinths, Ferns, Primula obconica, and Grapes were staged, which added to the interest of the meeting. A paper on Adiantums was read by Mr. H. A. Smith, illustrated by living and dried specimens. A slight discussion followed, and the meeting ended with the usual votes of thanks.

— THE opening meeting of the spring session of the READING AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION was held at the usual place on Monday evening last, when a large number of members assembled to hear a paper on "Salads all the Year Round," by Mr. Chas. Hott, the able gardener from Wokefield Park. Mr. T. Turton occupied the chair. The subject was treated throughout with considerable ability, and the discussion that followed proved how highly it was appreciated by the members. The Association is rapidly increasing in numbers, and there is every prospect of a successful session.

— THE STOTT INSECTICIDE DISTRIBUTOR.—We are informed that the inventions of Mr. S. H. Stott, insecticide and liquid manure distributors, have been taken over by a Company. This undertaking was registered last Friday with a subscribed capital of £10,000. The directors are Mr. Frank Hollins, J.P., Mr. S. H. Stott, and Mr. Clapham. At the monthly meeting of the Preston and Fulwood Horticultural Society, held on Saturday evening, a very warm tribute was passed to the inventor anent his machines, Mr. Stott having since received the following, signed by the Secretary of the Society, Mr. John Atherton:—"I am pleased to inform you that at a crowded meeting of the members of our Society held on Saturday evening, it was proposed by the Vice-President, and carried unanimously, that a first-class certificate be awarded you for your insecticide and liquid manure distributors, and which I am instructed to forward to you in due course." The Stott insecticide distributor will probably be tried at Chiswick during the ensuing season.

— MUSHROOM BED REFUSE.—The remarks of "Mushroom," page 556, last vol., induce me to give my method of dealing with this material, not that I think it will be of benefit to your correspondent, but it may be to others who, like myself, have the charge of poultry and other live stock. I find nothing better for laying on the floor of the poultry house than dry mushroom bed refuse. Like dry earth, it possesses considerable deodorising power, and if a layer is thrown over the floor twice or thrice weekly it may be allowed to accumulate for some time. When taken out it will be a more valuable manure than when it was put in. It should be used in the garden at once, or mixed with the manure heap, for if put into a heap by itself a brisk fermentation soon set in, and much of the ammonia it contains is given off.—T. S., *Henbury Hill*.

— THE following is the manner in which a London daily paper refers to the recent meeting of the ROYAL HORTICULTURAL SOCIETY:—"Fogs have affected English flowers as well as English people, judging

from the Show of the Horticultural Society at the Drill Hall, Westminster. Though there was a fine display of Ferns and 'Nepenthes Hybrids,' and even a fair show of Auriculas and Cypripedia, the early spring blossoms—Crocuses and Daffodils—looked as pinched and wizened as if they had been suffering from influenza, that to have pulled through at all is greatly to their credit. A rich violet Primula, 'El Spirito Saneto'; a 'Cella Ethiopia,' or Ethiopian Lily, of snowy whiteness; and a 'Lælia Aneeps'—white with brown heart, imported by the Liverpool Horticultural Company—were among the novelties." [The greatest novelty, we think, in connection with the meeting, was our contemporary's report.]

— FRUIT GROWING IN AUSTRALIA.—The latest report on the progress of Mildura gave the population as numbering 1200 persons. The necessary works for the efficient irrigation of 25,000 acres of land were nearly completed, and special steam machinery for ploughing and grubbing had already been obtained. In order to afford some idea of the work done on the settlement the following figures were published:—2600 acres cleared, 2200 acres ploughed, 2000 acres under fruit, Vines, and fodder crops; 24 miles of main channels completed, 30 miles of subsidiary ditches, 20 miles surveyed and in hand, 186 miles of fencing, and 4 miles of main pipes laid. Steps were being taken in order that Mildura might become a municipality, and nursery stock had also been successfully introduced, some of the settlers procuring supplies on their own account. Messrs. Chaffey Bros. had imported for contract planting more than 100,000 Vines, 20,000 Orange and Lemon trees, and 30,000 Olive truncheons.

— THE "tercentenary of the invention of the compound microscope" will be celebrated by a UNIVERSAL EXHIBITION OF BOTANY AND MICROSCOPY, to be held at Antwerp during the present year, under the auspices of M. Ch. de Bossehere, President, M. Ch. Van Geert, Secretary, and Dr. H. Van Heurck, Vice-President. It is proposed to organise an historical exhibition of microscopes, and an exhibition of the instruments of all makers, and of accessory apparatus and photomicrography. At the conferences the following subjects will be discussed and illustrated:—The history of the microscope; the use of the microscope; the projecting microscope and photomicrography; the microscopical structure of plants; the microscopical structure of man and of animals; microbes; the adulteration of food substances, &c. Communications are to be addressed to M. Ch. de Bossehere, Liège, Belgium.—(*Nature*.)

— WATERING PLANTS.—In many places this important work is left to young men, who do not take sufficient interest in their work. The consequence is that many plants are overwatered, which ultimately causes death. I know a head gardener who has a man under him (and whom he is obliged to keep, as he is considered a trustworthy man by his employer), who is a very careless waterer, so that one class of plants has to be given up entirely and cannot be grown, and he knows the fault lies with the waterer, but he dare not say so. Every plant under his charge has a good watering on Saturday, so that it shall not want it on Sunday. He is a good man to work, but should not have charge of delicate or costly plants. Many plants suffer by want of water, but far more are killed from excessive waterings, especially so during the winter, when root action is almost at a standstill.—HECTOR.

— TUBEROUS BEGONIAS AS BEDDING PLANTS IN PERTHSHIRE.—About the middle of last August, while on a visit to Glassengall, the seat of Mrs. Wallace, near Dunblane, Perthshire, I had the pleasure of seeing two most brilliant flower beds. They were filled with two-year-old seedling Tuberous Begonias of the large-flowered varieties, and all shades of colour. The seed was saved from plants in pots in the conservatory. The plants in the beds were dwarf and robust, the flower stems strong and standing well above the foliage, showing the flowers to perfection, and arresting attention whenever they were seen. The other beds and borders in the flower garden were filled with the usual plants, but they failed to attract notice when the Begonias were in sight. I have before seen beds of Begonias of the small-flowered varieties, but owing to their drooping habit and small flowers they never made the same brilliant display as those at Glassengall. Seeing that they do so well as far north as Perthshire, and 300 feet above sea level, it is encouraging for those who are in a more favoured situation to give them a trial. I am so convinced of their superiority over the Pelargonium as a bedding plant, at least in cold and wet districts, that I purpose procuring a stock, and should they succeed half as well as those I saw at Glassengall the Pelargonium will be partially superseded. Mr. McArra, the gardener—who is to be congratulated on his success with the Begonia

—told me that he grows them in a cold frame all spring, and plants out about the second week in June, taking care to give them plenty of room and air while in the frame, so as to have them robust when planted out. —GEO. GALLAHER, *Kilkerran Gardens*.

— *CELOSIA PLUMOSA PYRAMIDALIS*.—It is to be regretted that this beautiful plant is not more generally cultivated for autumn and winter decoration. For a few years past Messrs. Thomson, nurserymen, Birmingham, have devoted attention to the *Celosia*, and have grown fine specimens about 4 feet high, which have been well cultivated and flowered, but an effort was made to pot a lot of smaller plants in bloom for sale, and with great success. Even up to Christmas they had fine young plants to cut from, and during the autumn a number of well grown plants averaging about 18 inches in height in 48-pots. Their method of growing is this. To obtain specimens sow the seed in March in gentle heat, and repot and grow the plants in gentle heat until the end of May; then shift into larger pots, using a compost of loam, leaf soil, sand, and a little manure, taking care to give them the final shift before the plants show flowers. To have specimens in 48-pots sow early in July and keep the plants in 60-pots until they begin to show flower, then transfer into 48's. The *Celosia* is of easy cultivation, requiring similar treatment to Balsams, and their rich colours and graceful habit are strong recommendations. There are two varieties—*plumosa* and *spicata*, but the former is the best, and there are various shades of colour of each variety.—D. S. H.

— ROYAL METEOROLOGICAL SOCIETY.—The annual meeting of this Society was held on Wednesday evening, the 15th instant, at the Institution of Civil Engineers, Dr. W. Marcet, F.R.S. (President) in the chair. The Council in their Report congratulated the Fellows on the generally prosperous state of the Society, the past year's work, though not in any respect exceptional, having been thoroughly successful. The total number of Fellows is 550, being an increase of twenty-five on the previous year. The finances are improving, and the library is overflowing. Mr. Baldwin Latham, M.Inst.C.E., was elected President for the ensuing year. The retiring President (Dr. Marcet) then delivered an address on "Atmospheric Dust," which he divided into organic or combustible, and mineral or incombustible. The dust scattered everywhere in the atmosphere, and which is lighted up in a sunbeam or a ray from an electric lamp, is of an organic nature. It is seen to consist of countless moats—rising, falling, or gyrating, although it is impossible to follow any of them with the eye for longer than a fraction of a second. It is difficult to say how much of the dust present in the air may become a source of disease, and how much is innocuous. Many of the moats belong to the class of micro-organisms, which are frequently the means of spreading infectious diseases. Many trades, owing to their dusty nature, are very unhealthy. Dust, when mixed with air, is inflammable and liable to explode. After giving several instances of explosions due to fine dust in flour mills and coal mines Dr. Marcet referred to inorganic or mineral dust, and gave an account of dust storms and dust pillars in India. He then proceeded to describe volcanic dust, which consists mainly of powdered vitrified substances, produced by the action of intense heat. The so-called ashes or scoræ shot out in a volcanic eruption are mostly pounded pumice, but they also originate from stones and fragments of rocks, which striking against each other are reduced into powder or dust. Volcanic dust has a whitish-grey colour, and is sometimes nearly quite white. Dr. Marcet concluded with an account of the great eruption of Krakaton, in August, 1883. The address was illustrated by a number of lantern slides.

— SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, NOTTS, IN DECEMBER, 1889.—Mean temperature of month, 37.0°. Maximum on 17th, 53.8°; minimum on the 29th, 19.6°. Maximum in the sun on the 10th, 80.4°; minimum on the grass on the 12th, 15.1°. Mean temperature of the air at 9 A.M., 36.4°. Mean temperature of soil 1 foot deep, 38.3°. Nights below 32°, in shade, eighteen; on grass, twenty-five. Total duration of sunshine, twenty-five hours, or 11 per cent. of possible duration. We had seventeen sunless days. Total rainfall, 1.36 inch. Rain fell on thirteen days. Average velocity of wind, 8.7 miles per hour. Velocity exceeded 400 miles on two days, and fell short of 100 miles on eight days. A dull, calm, and rather dry month of about average temperature; only one fall of snow, and that did not lie long. Observations during the year 1889, 56 feet above mean sea level.—Mean temperature, 47.8°. Maximum on the 2nd of June, 83.6°; minimum on the 4th of March, 16.0°. Maximum in the sun on the 2nd of June, 135.8°; minimum on the

grass on the 13th of February, 0.6°. Mean temperature of the air at 9 A.M., 47.9°. Mean temperature of soil 1 foot deep, 48.3°. Nights below 32°, in shade, 73; on grass, 147. Total duration of sunshine, 1086 hours, or 25 per cent. of possible duration. We had ninety-two sunless days. Total rainfall, 25.71 inches; maximum fall in twenty-four hours on the 8th of March, 1.62 inch. Rain fell on 180 days. Average velocity of wind, 8.9 miles per hour. Velocity exceeded 400 miles on thirty-one days, and fell short of 100 miles on ninety-six days. Approximate averages for the year:—Mean temperature, 48.2°; sunshine, 1243; rainfall, 25.10 inches.

— THE WEATHER OF 1889.—The year has been, on the whole, a normal one except for a rather persistent deficiency of sunshine. The winter and early spring were cold, though without any exceptionally severe weather; then followed two warm months of May and June, which in turn were succeeded by a cold period lasting to the end of October. November was mild and December of about average temperature, the result being that the mean temperature for the whole year is a few tenths below the average. The total fall of rain is just about equal to the average; the largest excesses were in March and May and the largest deficiencies in June and November. April was also a wet month, while September and December were dry ones. There were only two falls of more than 1 inch in twenty-four hours; both in March. Sunshine was very deficient, and the only month in which there was an excess was June. Only 1086 hours were recorded in the year, which is just a quarter of the time the sun is above the horizon, and is 157 hours less than the average of the previous eight years.—JOSEPH MALLENDER.

— *The American Florist* announces the recent death of Mr. JOHN HENDERSON, and states that "With him horticulture loses one of its noblest representatives, loved and honoured by all who enjoyed the privilege of his friendship. Mr. Henderson was born in London, England, December 5th, 1818, where he received a classical education, taking a prize in Greek scholarship at the age of fifteen. He came to America in 1856, and settled in Flushing, N.Y., which continued to be his home until 1888. He soon became an authority in horticulture making a specialty of Roses, and is also author of a standard work on grasses. He delivered the first horticultural lecture ever given in the Cooper Institute, for which he received a silver medal. He was a life member of the New York Horticultural Society and the American Institute, constantly officiating as judge at the exhibitions of both bodies, and was also prominent in the Society of American Florists and Nurserymen's Association. He retired from active business last year. Mr. Henderson was an accomplished linguist, speaking four modern languages with fluency, apart from his acquaintance with the classics. Another account in the same paper says, "Mr. Henderson came to this country with a few hundred dollars in his pocket, the remnant of a large fortune lost in a disastrous business enterprise. He came to Jersey city and began business in a small way in forcing the finer kinds of vegetables for the New York market, a business of which he knew nothing, but his energy and strong common sense soon enabled him to equal and surpass most of his contemporaries. He gradually drifted from this business to that of florist, where he was more at home, for his training in his father's firm of E. G. Henderson & Sons, Wellington Road, London, had made him an adept in all florist operations, so that by the time he had been in business five years he became noted as growing the best plants and flowers sent into the city of New York. Although like most business men, he had reverses, yet he successfully weathered them all, and two years ago, having amassed a fortune, he sold out his immense Rose-growing establishment in Flushing, N.Y., to his manager, Mr. Chas. Anderson. As a man no one stood higher or gave a greater dignity to our profession than John Henderson. He combined the educated polished gentleman with the strong practical sense of a business man. Modest and unassuming to a fault, there are few men whose memory will be longer revered than that of our friend who has just passed away."

RŨG, NORTH WALES.

READERS of the Journal who are at all acquainted with Wales or Welsh history will at once recognise in the name of the hon. family of Rŭg—"Wynn" one of the oldest and most honoured of Welsh names, and as becomes the holder of such, the Hon. C. H. Wynn has elected to dwell in a spot closely associated with and surrounded by memorials of some of the most important events and scenes in the past history of Wales. In this neighbourhood did the famous Welsh prince, Owain Gwynedd, give meet to Henry II. on the monarch's incursion to subdue the Cymric spirit; and here also did Owain Glyndwr assemble his troops, unsubdued still, to go forth to meet Henry IV. More peaceful

and more honourable too, has a more recent Royal visit been, when our gracious Queen passed through the district and received a far heartier, though not perhaps warmer, welcome from her loyal subjects in Gwyllt Gwalia than that accorded the above-named monarchs. On the occasion of the recent visit just referred the Lord of Rûg was one of the most influential of Her Majesty's Reception Committee. From his renowned gardens also Her Majesty was presented with a magnificent basket of fruit that has become famous from the many eulogies bestowed upon it.

The mansion is reached by the Holyhead Road from Corwen over the picturesque river Dee, the haunt and delight of anglers. It is less than two miles from the L. and N.W. and G.W.R. joint station, and has two approaches from the Holyhead and Ruthin roads respectively. The iron entrance gates, all handwork and a considerable age, are very fine pieces of workmanship. The land in the vicinity of the hall being somewhat low lying necessitated that it should be on a raised platform or terrace. The surroundings are well furnished with ornamental trees and shrubs, and the park throughout is finely wooded, and contains splendid specimens of Oak, Elm, &c., one especially noteworthy being known as "King of Rûg Oak." Among the many hardy plants in the

many beds and borders of the usual summer bedding kinds. The broad walk that runs through this garden from the hall to the kitchen garden makes a splendid promenade. Leaving this we enter the kitchen garden a well managed one too. On three sides are walls, which are furnished with Plums, Cherries, Pears, and a few choice Apples, mostly young trees, in a border 12 feet wide. These, in common with espalier and pyramids in the squares, give a good account of themselves generally, and their produce is not unknown on the boards of our leading exhibitions. Mr. Bennett, as a rule, musters a dish of Plums in good condition for a collection of fruit at the Liverpool autumn Show, about the third week in November.

The fourth side of the garden is faced by a range of glass structures, No. 1 being a Peach house (iron), a good roomy house, with Peaches Royal George and Barrington, and Nectarines Pine Apple, Lord Napier, and Violette Hâtive, all beautiful trees. They are evidently well cared for. No. 2 is a companion structure where Black Hamburgh, Foster's Seedling, Madresfield Court, and Gros Colman Grapes are grown in inside borders to perfection, and would be an argument in favour of inside borders but for the fact that all the other Vines are grown in outside borders and do equally well. Mr. Bennett adopts an original

FIG. 11.—RÛG, NORTH WALES.

extensive pleasure grounds that do well, the Rhododendrons might be mentioned; they flourish exceedingly well, so do many of the flowering shrubs. There is also a splendid collection of hardy bulbs throughout the shrubberies. The accompanying view (fig. 11) will afford a better idea of the beauty of the lake and its banks than my pen can do. Ornamental bridges spanning the water lead to the chapel in the grounds, and not far from the chapel is St. Sulien's Well, interesting to antiquarians. The church at Corwen is dedicated to this saint. Adjoining the mansion is a lofty conservatory, where specimen Tree Ferns, Palms, &c., find a permanent home; miscellaneous flowering plants afford a brilliant display beneath the graceful drapery of various climbers that grow luxuriantly and adorn the upper regions of the house.

Roses do here remarkably well in beds devoted to them, and one long row of climbers trained on wires is quite a feature. Behind this there is a most interesting border devoted to the now popular but long-neglected hardy perennials. Here from early spring until late autumn there is a good floral display, commencing with spring bulbs, and continuing with Pyrethrums, Pæonies, Phloxes, Asters, &c., until autumn bulbous plants again make themselves conspicuous. In the front of the Rose trellis is another border of equal length, which is annually carpeted, and affords relief to the masses of colour in the

and very wise method with most of his inside borders. After making his borders good in spring he places pebbles or roundish stones closely together on the soil, or manure where used, and thus where pots have to be stood or trampling to be done the border does not become soddened, and when watering also, instead of a puddle the house has a clean and tidy appearance; and, again, where exposed at all this method prevents evaporation and encourages the roots upwards, as will be seen by removing a stone when the trees are in action. A small but pretty and useful fernery is entered from the back of this house. Ferns for cutting purposes are grown densely on walls, an arrangement that saves pot plants, and is on that account a consideration where the demand is great. No. 3 is the late vinery, the principal sorts are the Alicante, Lady Downe's, and Muscat of Alexandria. No. 4 is also a vinery. Here Black Hamburgh is found in company with Buckland Sweetwater, Duke of Buccleuch, and Alnwick Seedling. The latter is a favourite sort, and seems to be growing in favour generally. All methods of pruning and training are adopted by Mr. Bennett, and all successfully. As we pass onward by a very useful heated lean-to pit used for forcing Strawberries, we come to what was recently a Peach house, and is now being converted into a Fig and Rose house. Figs to be grown on back wall, and Tea Roses in pots in front to meet the demand for the popular flower. The next is a span-roofed stove

containing table plants, winter flowering plants, such as Poinsettias, and planted out in centre bed are some capital Gardenias.

Outside the kitchen garden is another block of houses, No. 1 range being newly built, consisting of a Camellia house and stove—a fine lofty structure 75 feet long and 20 feet wide, well adapted for large specimens. Camellias are planted out in the centre bed, slate stages on the sides for Azaleas. A fine specimen of *Todda superba* is looking its best in this house, and in the adjoining compartment are some fine specimens of Crotons, Palms, Eucharis, and Nepenthes. There are also Water Lilies and a few Orchids. The paths in this range are of cement, possessing the merits of being comfortable, durable and clean. Cucumber and Melon houses we pass on our way to the Pine stoves. Here we find this family represented by Queen, Prince Alfred, Smooth Cayenne, and a few Charlotte Rothschild. Pine culture being one of Mr. Bennett's foremost acquirements, it is needless to say that they are in splendid condition. Ranges of heated and unheated and dung frames all doing good service, as testified by the appearance of their several occupants, complete this block, but facing it on the kitchen garden wall is a new lean-to house for the cultivation of Pears, Plums, and late Peaches, all to be planted out, protection to these trees being necessary, the climate not being quite what a gardener would desire. Under such conditions it is all the more credit to produce in all departments, in and out, such favourable results as are here obtained. Nor are the results, like the proverbial light, hidden under the bushel. Encouraged by the enthusiastic patrons of horticulture, the Hon. Mr. and Mrs. Wynn, Mr. Bennett annually succeeds in giving account of himself with his Pine Apples, Grapes, and collections at such fixtures as Shrewsbury, Liverpool, summer and autumn. "May his hand not soon forget its cunning."—BRADWEN.

ROYAL HORTICULTURAL SOCIETY.

JANUARY 14TH.

SCIENTIFIC COMMITTEE.—Present: D. Morris, Esq., in the chair, and Professors A. H. Church, H. Marshall Ward, Drs. Hugo Müller, M. T. Masters, Messrs. G. F. Wilson, W. H. Blandford, R. McLachlan, F. Pascoe, Albert Michael.

Seakale Roots.—Professor Ward reported that the specimens submitted to him at the last meeting were affected with the slime-fungus (*Plasmodiophora*), a fungus which does great damage to the roots of Cruciferous plants.

Canker in Apple Trees.—The same gentleman reported on the specimens referred to him at the last meeting, but which presented no unusual features.

Acari of Sugar-cane.—Mr. Michael reported on mites affecting Sugar-canes in Barbados. Contrary to anticipation, the acaroids belong to the family Oribatidae, and either to the genus *Notaspis* or to *Damaeus*, having the appearance of the former, while the internal anatomy is more like that of the latter genus. The species is allied to the English *N. lucorum*, but is probably undescribed. The creatures in question are strictly vegetable feeders, but have not hitherto been considered as inflicting any material damage to living flowering plants, being found more particularly on moss lichens. Mr. Michael recommended that specimens of the infected cane slightly moistened, with the living *Notaspis* on them, should be put into a tin box, sealed down to prevent drying, and thus forwarded in a suitable condition for further examination; other Acari, of the genus *Tarsonymus*, and of extremely minute size, are known to be injurious to Sugar-cane. The species of *Damaeus* are found under the bark of trees. Judging from analogy only, the mites in question would not seem likely to do much injury to living canes.

Dactylopius (Mealy Bug).—Referring to a communication made to the Committee on December 10th, Mr. Morris now read a letter from Professor Riley on the use of rosin washes for bark lice. "If," says Mr. Riley, "the insect is a *Dactylopius*, the Alexandrians cannot do better than use one of the rosin washes with which we are spraying *Icerya* so successfully in California." The following extract from "Insect Life" contains a good formula for the purpose:—

Rosin Wash for Red Scale.—In accordance with instructions, Mr. Coquillett has been making experiments with this wash against red scale (*Aspidiotus auranti*), and after twenty different tests made with various preparations, from July 17th to August 8th, the one which gave the best results was found to be composed of rosin, 20 lbs.; caustic soda (70 per cent. strength), 6 lbs.; fish oil, 3 lbs.; and water to make 100 gallons. In preparing this wash the necessary materials were placed in a boiler and covered with water, and then boiled until dissolved, and stirred occasionally during the boiling. After dissolving, the preparation was boiled briskly for about an hour, a small quantity of cold water being added whenever there was danger of boiling over. The boiler was then filled up with cold water, which mixed perfectly well when added slowly and frequently stirred. It was then transferred to a strong tank, and diluted with water to 100 gallons. Neither the leaves nor the fruit was injured, while a large proportion of the scales were destroyed. Those which escaped were either on the fruit or the under side of the leaves. The cost of the wash is 80 cents. per 100 gallons, or four-fifths of a cent. per gallon. An Orange tree 16 feet tall by 14 feet in diameter was given 14 gallons. This, however, seems to us to be an unnecessarily large amount, but upon this basis the cost of spraying per tree is 11·2 cents.—(From "Insect Life," Oct., 1889, p. 92, U.S. Department of Agriculture.)

The Winter Moth.—Mr. Wilson called attention to a communication

in the *Hereford Times* of November 9th, 1889, as to the efficacy of greased bands as a check to the insect, and wherein Mr. Cranston says:—"I consider that the greasing process which is being adopted is injurious to the bark of the trees, especially to young trees. To the older trees it may possibly not do much harm, but I believe the old plan of painting the trunks of the trees with a solution of quicklime is the best. Some use soot with the lime, but I don't know that the soot is of much consequence except to dull the white glare of the lime. The painting should be done in the autumn."

Mr. McLachlan pointed out that the proposed trap to be affixed to the lamp-post, in the case of suburban fruit plantations, would be practically useless, as only the male insects would be thus captured, the females being nearly destitute of wings, and incapable of flight. All attempts at stamping out the winter moth should be directed to the destruction of the females, which are capable of depositing eggs for many generations in succession without the intervention of the male. The capture of myriads of males would not have the slightest appreciable effect on the fertility of the untrapped females.

Monstrous Cypripedium.—Dr. Masters showed drawings of two *Cypripedia*, in one of which the three sepals were separate, as in most Orchids, whilst in the others there was an adhesion between the median sepal, the lateral petal on the left side, and the lateral sepal on the same side, the adhesion of these parts being accompanied by corresponding adhesion of the labellum to the right lateral petal. The median stigma, G, 1, of the Darwinian notation, was also petaloid.

Keteleeria Davidiana.—Dr. Masters showed a cone sent by Dr. Henry to Kew, from Ychang, and which has special interest as being intermediate in character between the Spruces (*Picea*) and the Silver Firs (*Abies*). It is congeneric with *Keteleeria Fortunei*, a tree introduced to this country from China, but which is too tender for general cultivation.

It was announced that the next meeting will be held on Feb. 11th, after the annual meeting, and therefore possibly a little later than the usual hour, 4 P.M.

HALL FOR HORTICULTURE.

WE are very pleased to see you are giving publicity to suggestions as regards a hall for horticulture. After reading the various comments respecting it many must have been surprised at the wide difference of opinion as to the best method of attaining the object in view. Dr. Masters, in reviewing our circular, which proposes to solicit donations from the wealthy who have horticulture at heart, remarks:—"Like our friends we too hope to see the day when we shall have 'a hall worthy of our great nation,' and one which shall be available not only for the meetings of the Royal Horticultural Society, but of all the special societies, of the library, of the Horticultural Club, and of the charitable societies connected with horticulture. This has been a dream for many a long year, but when we see the proposal being sent broadcast we begin to hope the dream may be fulfilled." Our friend, Mr. Hibberd, says if our suggestions are carried out it will be a mockery, delusion, and a snare, and almost commands his friends not to have a hand in such an awful and dangerous work, yet the very same means we suggest are adopted to build nearly all our churches, chapels, and many other public buildings; and how your readers will understand and reconcile the statements coming from two such distinguished men is beyond our comprehension. However, we are delighted to think that we have been the means of publicly uncovering the light which that gentleman (Mr. Hibberd) has so long kept under a bushel, be it a rush-light or a star of the first magnitude yet remains to be proved. If he alludes to us as the friends who heard of his scheme, a sort of pseudo-joint stock market, co-operative store company, or some such kindred title, our friend was never more mistaken in his life. He should be sure and certainly show some evidence before putting forth such statements. Mr. Hibberd also speaks of a resolution he put to the meeting in 1888 and lost. A year before that in the side room at the Albert Hall we asked the Council not to finally engage the Drill Hall until the Fellows had time to consider its advisability; and again at the same meeting Mr. Hibberd mentions we proposed that we should ask the Crystal Palace Company. This was also lost; consequently here is far more ground for considering that his ideas were borrowed from us. He was present on both occasions, and probably heard us converse with many about procuring a site on the Thames Embankment. We think we are safe in saying very few projects can be pointed out that have had a happy time where capital had to be borrowed for horticultural purposes. Many have had, we know, a disastrous ending; no one knows the extent of such better than our friend, yet he almost makes it appear as if the Royal Horticultural Society is not doing as much good work and as deserving of sympathy as any of the Polytechnic institutions whose eleemosynary donations are to the extent of £50,000 a year in London.

Our friend is so definite and determined on this point we are afraid if some well-wisher was to bequeath us for this hall a thousand or so in the same way as Mr. Davies, Mr. Hibberd would by his teachings be for immediately returning such donation, and saying it would lower the dignity and injure the very foundation of our Society. Every farthing to build this hall must be obtained by its own commercial pursuits, and of course be called "The Royal Horticultural Hall Trading Company Unlimited." The very thing, in our opinion, to destroy its charter, character, independence, and all purposes for which the Society is intended. However, judging from the several inquiries as to the sort of

building needed, our hopes are more and more strengthened that we shall have assistance from some amongst the great and wealthy of this country, and so place the Society in a comfortable and becoming building equal to those possessed by horticulturists in Belgium and America, to enable us to look up with pride and pleasure, and feel that the Society is advancing in the improvement and encouragement of the earth's productions.—H. CANNELL & SONS.

ON Tuesday, January 14th, I had an opportunity of discussing the proposal with several friends at the meeting in Westminster, and I am well satisfied with the tone that prevails amongst men who are at once leaders in horticulture and in great business undertakings. The hopeful spirit that now appears in the consideration of such a project contrasts strangely but pleasantly with the despondency that years of forbearance and vexation had engendered in the later days of the unfortunate occupation at South Kensington, when the R.H.S. exhibited symptoms that by some were mistaken for approaching dissolution. It was then foreseen, as it is now, that in the event of the old phoenix renewing its youth it would need a nest to sleep in and a sky to fly in; and it was neither this nor that man's bap to conceive the idea of a home for horticulture. But so far as the matter obtained casual attention, the general opinion appeared to be that the Society must provide for itself, and therefore must wait until rich enough. Whether wisely or unwisely, I certainly did at times urge that the Society itself need not be concerned about building and incurring debt; all it need do would be to pay a reasonable rent for a suitable place, and as for the rest, the commercial principle might be trusted in this as in other things. Messrs. Cannell & Sons profess to have originated the idea of a hall for horticulture, and I should be very sorry to damage their sense of satisfaction, and as I have made no such claim, there need be no conflict, save, indeed, as to the ways and means, for at that point I must leave them to form their party and develop their plans. But I will warn them in time that a sum of from £25,000 to £50,000 will be required for the thing that is wanted, and £1000, perhaps, might be, with good management and great effort, scraped together, and then—Well, beyond that they probably would not proceed, and the end would be, as Messrs. Cannell hopefully anticipate, "a disused church or chapel," to be "utilised so that the Society could call it their own." I have no ambition to appropriate the idea; Messrs. Cannell & Sons are, in respect of any possible purloining on my part, as safe as if they had kept their dignified ideas entirely to themselves.

It does not appear that in the whole of this great metropolis there is any such respectable centre for the association of men of science and lovers of such arts as horticulture may be honourably associated with, whether for corporate action in a common cause, or for their several separate labours, discussions, and festivities. The peculiarities of the negative case were forced upon the attention of the gentlemen who went forth to find a place of meeting for the R.H.S., and could find nothing better than the Drill Hall in Westminster. There are any number of places in which men may meet conveniently and with light enough for the display of plants, but there is usually a serious objection of no subtle nature, but flagrant and notorious. The case does not affect us solely; it is one of general public interest, and bears directly on the round of recreations that are in daily demand, and abundantly pay their way in proportion to their merit and the cleanness of the management. Establish a handsome hall in a spot commanding a constant flow of traffic; here initiate daylight occupations for the scientific, and evening entertainments for the people, and you will not fail of your reward, which will doubtless correspond with your deserts, and will crown good management with complete success. Our fortnightly meetings would soon acquire renown in a place reasonably adapted for them, and a flower show under the electric light, with suitable accessories, would do for horticulture what has never been done yet—we should outdo the "palmy days of Chiswick," minus the dreadful weather that first abolished Vauxhall and then applied the surplus of its savagery to the best flower shows of this nineteenth century. A thousand uses for such a hall would arise as it acquired a name and a place in the economy of society, and the life of the thing would be in its independence and respectability. As an arena for lions and lambs, as a home for the trapeze and the wire rope, as a mere shelter for so many drinking hars, it would be a failure first, and finally a disgrace and a curse. That it would fail if perverted from the purpose for which it is proposed cannot be doubted, and upon that assumption may be founded our expectation of success. We want a beautiful building, with sufficient space for half a dozen meetings to be held simultaneously, and a noble hall abundantly lighted both by day and night, with, perhaps, a hijou plant house, in which subjects requiring to be on the spot for a few days or more might be kept under observation, and flowered or fruited without disturbance or danger of transit at unseasonable times. The Weather Plant offers an example. It has been under operation for forecasting in a house in the R.H.S. Gardens at Chiswick, and has been seen by some dozen or score of persons only. In a conservatory on the Thames Embankment it would have been visited by hundreds, possibly by thousands.

The kind of institution I have in view should be somewhat of a costly affair, and the requirements of the R.H.S. should have direct and primary attention in the original design and its several details. It need not be said that under present circumstances the R.H.S. could not pay for such accommodation as it is proposed to provide, but it is a fair speculation that it soon will be able. In the meantime I wish this point to be kept in view, that the edifice suitable for horticulture will be suitable also for many other purposes that may be honourably and use-

fully associated with horticulture. There is no such ball as we require, but there are a thousand uses for such a thing from the moment you have established it. To be safe against perils that are better understood than explained, you have but to adopt as the foundation of the business that the edifice shall be used only for such purposes as consist with the advancement of science, art, and literature, and all the rest will turn on management.—SHIRLEY HIBBERD, *Kew*.

[We are authorised to say with regard to the suggested Hall that the matter has been before the Council for the greater part of the past year. A Committee of the Council was appointed in the autumn for the purpose of elaborating a scheme, and they hope soon to be able to bring something tangible before the Fellows and the general public. It will then altogether depend on the amount of financial support which the Council receives whether the project be carried to a successful issue or not.]

CHRYSANTHEMUMS COMMERCIALLY.

WHEN the varieties are well selected, the plants well grown, and the time of placing the crop in the market is well chosen, Chrysanthemums pay fairly well. They are essentially a catch crop, because they occupy house space which otherwise would in all likelihood be unfilled, while they have the further advantage of brightening an otherwise dull period, and after having fulfilled this duty may be consigned when fresh to the commission agent at a profit, instead of going to the compost heap when decaying, at a loss. Gardeners too often make the mistake of sending any kind of produce to market which is not wanted or not good enough for home use. True, the quality offered to the public by shopkeepers and the prices charged for the same might lead to the conclusion that anything is good enough, but when it comes to be a question of getting rid of produce at a fair price in the glutted market, then the best variety and the best quality must go together.

In a private garden it is, of course, impossible to select too closely. for Chrysanthemums are, like Roses, possessed of great individuality, and this indeed is one of their greatest charms. But while growing a comprehensive selection, it is at the same time judicious to cultivate merely one or two each of these and increase the number of profitable sorts, which are also the best of decorative plants. Ahead of all stands Elaine, and if it were merely a question of growing the purest and best white, then we might be well satisfied with this alone; but in some seasons it fails to set its buds, and consequently it would be suicidal to depend on it alone. In some seasons, also, it is earlier than other sorts, while, as a rule, some of the earlier varieties are of value before this is in. Next to the above comes Mrs. G. Rundle. Good blooms of this sell well, and the crop is always large, which is, of course, a point of importance. Fair Maid of Guernsey, owing to its lateness and great profusion, is also valuable, though not so good as either of the above. Lady Selborne is rather early to be of much value, but it carries such an enormous crop of flowers that it is well worth growing. Of yellow varieties, Peter the Great is of great value. It may be had either in midseason or late, and for colour, size, shape, and profusion of bloom it leaves nothing to be desired. Mr. Gienny and Mrs. Dixon are also good. Mr. Bunn is a fine early sort, but not so good as Mrs. Dixon, and very free and good is Elsie, which, moreover, stands well. Of coloured varieties, Source d'Or is in all respects fine. Of a darker shade is Reverie, also fine, and earlier is W. Holmes. I have not found the Teck family do well in the north. Some often can be had as late, and are much more free. Worth growing also are Felicity and Mrs. Forsyth as midseason whites; while Lady Margaret, though not a free flowering sort, throws very fine blooms very late in the season.

Of extra sorts of yellows, Chevalier Domage is fine, and Phoebus and Golden Queen may be profitably grown. Annie Lowe, though very light in shade, promises well, and the yellow Ethel should also be grown. There are several good coloured sorts, thus Cullingfordi, L'Ebouriffée when well grown, very fine as a late sort is Val d'Andorre. But it is important to note that a dozen blooms of one sort and a dozen of another are not wanted so much as many dozens of two or three good sorts at a time.

It will not do to allow the plants to grow without giving every attention to their wants and the requirements of the variety. Thus it will be found that cuttings selected and rooted in November or December will not only yield more blooms than spring struck cuttings, but the quality of the blooms will be better. Then an early propagated plant can be pinched early in its career, and three or four shoots produced instead of one, without in any way affecting the quality of the blooms. Another point of importance is to thin out the weak shoots which break from the main stems towards autumn. These weak breaks never produce good blooms, and they affect the others injuriously, while their removal has a beneficial effect on those left. From three dozen to fifty blooms is a good crop to a plant, and the power of a particular plant to develop a given crop must be estimated so as to thin to the desired number. And again, when the buds are set, the thinning of these must be seen to, so that

every bloom may be fully developed, and with a long, clean stem when cut. Blooms thus prepared are sure to be above the average, and may be depended upon to bring a remunerative price. But there are occasions when it is unsafe to put even good blooms on the market. The past season was a case in point. Fairly good blooms were selling at 3d. a dozen, and much was unsaleable at any price. The only course open in such circumstances is to keep the bloom. Varieties differ considerably in their keeping qualities. Thus, Lady Selborne keeps pure and good for a long time; Elsie also keeps well, the flowers changing to white with age, but Elaine rapidly changes to pink, and the Rundle family have the same fault. When it is expected that flowers will be over-plentiful, no better thing can be done than just to keep ventilators open night and day, and to shade from sunshine. Every day saved thus makes the chances of keeping greater in an increased ratio, for by the end of November buds unfold very slowly indeed unless fire heat is applied. If flowers are open, then the only thing that can be done is to shade heavily, to keep a dry atmosphere, and to give as much air as possible, giving fire heat only in very damp weather and during frost, but always with ventilation. Ten days to a fortnight can be gained in this way, and when the flowers are quite fresh they may be cut and kept in a dry, cool room for a few days longer; but, if old, they must not be so kept. A fresh bloom keeps well for two to three weeks, while an old bloom will not last as many days.

Chrysanthemums are easy to pack, and travel without damage if judiciously handled. A very good plan is to bunch into sixes or dozens with the blooms facing one way, and each one clear of its neighbour, so that no one presses on the other. These, again, may be further bunched into six dozen lots, always keeping them flat. Boxes just deep enough to hold one layer are best, and about twenty-four dozen in a box. A sheet of paper is laid in the bottom of the box; on this the flowers and any open spaces filled with soft bracken fern, then another sheet of paper on the top, and the box is ready for the lid, which must not be nailed, but tied. If possible, one variety or one colour should occupy each box.—B., *North Britain*.

REFLEXED AND ANEMONES—OLD AND NEW.

EVIDENTLY, while for show and exhibition purposes large blooms will still be the grand aim, everything else being equal, large numbers think the vigorous, free growing, and floriferous varieties, though small, should not be wholly neglected. Of this character

Julie Lagravère (Salter), more than thirty years in existence, and still one of the richest crimson reds, may be taken as an illustration. There are many in the Pompon section, such as Mdlle. Marthe, Sœur Melanie, and Mdlle. Elise Dordan, often seen larger, still in the National Catalogue it is retained in the reflexed class. Comparatively small though it thus is, is there any who have won honour and fame with "Julie" as a specimen plant, or a telling object in a group, who would like to see it lost? Of the same attractive character, but usually small size, are Phidias and Felicity, rarely seen on an exhibition board, but very undesirable to lose from the still limited reflexed class.

Emperor of China.—As I am on this subject I should like to enlist some sympathy for my oldest Chrysanthemum acquaintance. I hardly care to remember how many years it is since I first saw it adorning the sunny wall of a cottage in the end of October, and yielding for weeks an endless profusion of perfect blooms. It competes with the Christines in hardiness. Indeed, I have seen both flowers and foliage frozen hard, and after a thaw go on growing and blooming seemingly none the worse for the experience. I am sure Mr. E. Molyneux, who has generally a good word for outdoor Chrysanthemums, has seen very fine blooms, as no doubt have many of your readers. A great many years ago, in my early Chrysanthemum growing days, I sent the Editor some blooms cut from a south wall. I thought, like Dominy Sampson, "Prodigious!" and asked him if he ever saw anything nearly so good. He blandly assured me, however, that he had; but then warmly commended it, as I do now, with those already named, to any beginner who may wish a profusion of outdoor blooms for cutting from. The same generally applies to all reflexed.

Miss Annie Lowe (Anemone).—I have had two forms and colours of this from two most respectable firms, and both fairly resembled the sporting parent Lady Margaret. One had a triple row of guard florets, full centre, and was light yellow in colour; the other a single row of petals at the margin, not so full disc, and was pale yellow generally. It is a good thing.

James Weston (Anemone).—Introduced direct from China, as most of the good things are, I had late, and is only now in bloom. Should be very effective as a show flower. The guard petals are long, drooping, and pure white, while the disc is full and bright yellow. It is this combination of colour that makes this very fine new variety so welcome an addition.—W. J. MURPHY, *Clonmel*.

SHEFFIELD AND WEST RIDING CHRYSANTHEMUM SOCIETY.

A VERY interesting and instructive discussion initiated by the Committee of this Society was obligingly sent to us some time ago, and has not been deprived of any of its value by unavoidable delay in its publication. Mr. W. K. Woodcock spoke first on "New Chrysanthemums: their Habit, Height, and Fitness for Exhibition Blooms," and Mr. James Udale addressed the meeting on "Damping of Blooms."

Mr. Woodcock said he would commence his remarks by referring to the Japanese varieties. The French raisers have sent over such numbers of new varieties, many of which have turned out worthless, that they are beginning to ruin their own trade by it, and causing the English

growers much trouble and inconvenience in selecting the best. The first place among Japanese must be given to Mrs. Alpheus Hardy. It came from America, though it was originally an introduction from Japan, and has been shown by Mr. Ware. It has been well illustrated in the *Journal of Horticulture*—the best and most faithful representation. The colour of Mrs. Alpheus Hardy is white, and it is undoubtedly a most beautiful and valuable flower. I was much astonished last season at the demand for Avalanche, another beautiful new white Japanese. It was hardly to be had, and all the leading men had great difficulty in keeping a stock in hand. There must have been thousands of Avalanche sold last season.

Etoile de Lyon is one almost certain to be in great demand during the coming season. I have heard it described as a beast, but it has a very striking effect in a large stand of Chrysanthemums. The demand at the present day is for large flowers, the larger the better. In Etoile de Lyon we have the largest Japanese that can be shown of a presentable character. There may be some doubt whether it or an older variety, W. G. Drover, claims the pre-eminence for size, but I think it is the largest flower we have yet had. Before it is fully expanded the flower is very pretty, and of a very bright pink. It afterwards takes a dirty white appearance. As an exhibition flower it has a very telling effect on a large board. Sunflower, which was sent out last year, has proved itself an exceedingly good variety, and has given general satisfaction during the past season. It is a bright golden yellow, and will certainly take front rank among exhibition flowers. Mdlle. Louise Leroy, a fine white Japanese, grows to a moderate height, and produces a well built up deep flower, something after the character of Florence Percy.

George Daniels is one of the most pleasing flowers I have seen among the new ones. It is a dwarf grower, short-jointed, and sturdy, much after the character of Avalanche, a habit of plant which deserves to be encouraged in our new varieties. The colour of the flower is a pleasing soft shade of pink, of good size and form. The outer florets turn up slightly, and give the bloom a somewhat cup-shaped appearance.

Sarah Owen can scarcely be called a new variety. During the present season it has been on most exhibition stands I have seen exhibited. Its parentage will give it credit for being a good flower. It was raised as a sport from Madame J. Laing. Mrs. Falconer Jameson is one of which great results have been expected during the present season. It has dark green foliage, large and deeply notched, of dwarf habit like Avalanche and George Daniels. It produces a large bloom, but this year it has not flowered well. I have only seen one good bloom exhibited. Plants were much in demand at the beginning of this season, and as a consequence it was propagated rapidly. I think we may look for better results next year. The bloom is similar to Val d'Andorre, but is larger and more compact. Its greatest beauty is in its foliage and habit of growth.

Stanstead Surprise is in very few hands yet. There is no doubt from what has been seen of it that it will be of great value to exhibitors. It is quite distinct in appearance and character. The ends of the florets have a pleasing sort of pearly white tint, and also they have a curly character, which with the white tip gives a pretty appearance to the bloom generally. Growers have not had the best opportunity yet to produce the best plants and large flowers. With another year's growth a really first-class flower will be produced. It is evidently one of the earliest, and exhibitors will have to treat it in the manner they do other early varieties. It comes with Comte de Germiny and Mdlle. Lacroix.

Album fimbriatum was sent out by Messrs. Laing. There were many flowers shown this year, and it is a first-class variety when seen in good character. It is not so pure a white as some others, but still it is a handsome bloom, very fine florets, full, narrow, almost quilled at the end, which gives it the character of fimbriated. M. Bernard, which nearly all exhibitors have, is a most beautiful flower, and the colour of it is undoubtedly a great improvement upon Madame de Sevin, and is likely to oust that variety. It is a first-class front row variety, and is certain to attract and please everybody.

Thomas Stevenson is a reliable variety—a sport from the old variety Criterion. Everybody who has grown that variety knows what a good one it is; therefore a sport from it is certain to be valuable. It was shown at Sheffield for the first time last year for the purpose of gaining a certificate, but by some mistake was overlooked; but when shown at the Royal Horticultural Society's Committee meeting it was awarded a certificate.

Another variety which is bound to be useful is Mrs. S. Coleman, a sport from Princess of Wales. This is the most reliable and best of incurved varieties that can be grown. Any good sport from Princess of Wales is certain to be popular among exhibitors. Two of the best incurved varieties were introduced last year. There was scarcely a winning stand of twenty-four but what contained one or both of these—Violet Tomlin and Miss M. A. Haggas. The latter is a sport from Mrs. Heale, the other from Princess of Wales. Violet Tomlin is a most thoroughly distinct and beautiful flower. A splendid bloom was shown at Leeds; it was a model flower, fit to be present anywhere and in any company. The colour is distinct from anything we previously had in the incurved section. Miss M. A. Haggas does not come quite equal in form to Violet Tomlin, but takes after Mrs. Heale. It is of a bright yellow colour, and is bound to be valuable and take the place of the old variety Jardin des Plantes, which is difficult to get large and smooth enough to occupy a good position on the show board.

Mr. H. Shoemith has not appeared on many show boards so far, and has not produced first-class blooms. I am strongly of opinion that

it will do so. Exceptionally good in floret, it evidently has the build and character of Mr. Bunn. The plants seem to have lacked in stamina this year; that will only be owing to the fact of over-propagation last spring.

Amongst Anemones we have had many good varieties introduced. Madame Robert Owen is a most beautiful white flower, more beautiful than the long-time favourite Lady Margaret. James Weston is a good large bloom, useful for the show board. There are several other good Anemones, but I hope someone else will supplement my remarks on the best and newest introductions in Chrysanthemums of last year.

Mr. Hague, the Chairman, then invited discussion on the subject, remarking that they had been favoured with an able paper. Mr. Bacchus and Mr. Udale recommended Condor as a useful white Japanese, the latter observing that it was bold in character, broad in floret, and would certainly make a powerful exhibition bloom. He endorsed all that Mr. Woodcock said, he had given a very exhaustive list. There

passed to Mr. Woodcock on the motion of Mr. Ledger, seconded and supported by Messrs. Hardy and Broughton.

(To be continued.)

HOLBORN FAVOURITE MELON.

WHEN Mr. A. Pettigrew of Cardiff Castle Gardens describes a Melon or anything else as being good it may be taken for granted that it is something worth growing, for his standard of excellence is a high one. He is an expert grower of Melons, and we heard of a remarkable crop he had last year. Considering the fruits meritorious he sent a specimen to Messrs. Carter & Co. for comparison with others, and the firm appears to have been so impressed with the variety as, like the boy and the soap, they could "not be happy till they got it," though we are given

FIG. 12.—THE HOLBORN FAVOURITE MELON.

was one he should like to add called Buttercup; Veitch's, he thought, were sending it out. It was the prettiest yellow he had yet seen. It was a broad petalled variety, and very effective. Violet Tomlin he had seen grown to perfection, also Miss M. A. Haggas, one of the most powerful exhibition flowers. Mr. H. Shoemith is a good exhibition flower. Mr. Woodcock endorsed the good opinions expressed about Condor, which he had omitted to mention.

Mr. Bacchus, who represented Mr. Lambert, an exhibitor, impressed upon growers the desirability of securing the varieties mentioned. M. Bernard was superior to anything he had seen this year. He should advise exhibitors to secure five plants of Miss M. A. Haggas and three of Violet Tomlin.

Mr. James Harrison asked what was thought about Madame Baco. He really classed it as an Avalanche, only different in colour. It was a deep colour something grand, and had been his favourite. He had not heard any mention made of Stanstead White, which he considered a very good one that had done well with him. Mr. Molyneux said last year he did not think much of it. He said that Madame Baco produced a very good and pleasing flower, and if the first crown bud could be caught he did not know what it would be. A vote of thanks was heartily

to understand that Mr. Pettigrew did not send it as a new variety for sale. It is one of his improvements in Melons, and he describes it as follows in Carter's "Vade Mecum":—"Fruit of the largest size, roundish ovate; rind, lemon colour, heavily netted; flesh, greenish white; flavour, sweet, melting, and juicy; habit of plant, strong and vigorous; a free setter and a great bearer. It is one of the handsomest and best-flavoured Melons in cultivation, and was greatly admired by all who have seen it growing here." Accompanying that description is the illustration (fig. 12) that we are permitted to use in our columns.

EARLY TOMATOES.—The Tomato is now such a great and general favourite that many desire to possess it all the year round, and although it is difficult to secure a supply to this extent there need be no great gap in the circle, as the late ones are not quite over, and by sowing some of the earliest now new fruit may be gathered in March, or by Easter at the latest. The large fruiting kinds must be avoided for very early crops, and their culture at this time may be commenced wherever possible, as the fruit will be greatly valued on the table, and, if neces-

sary, remunerative in the market. From one to two dozen plants may be as many as can be accommodated thus early. These might all be sown and raised in a 6-inch pot, and they would grow rapidly in a temperature of 65° or 70°, but when the time came to pot them singly they would receive a check that would throw them back for a fortnight in their time of gaining maturity. To avoid this we sow each seed singly in a 3-inch pot, and then pot them without disturbing the roots or checking them in any way. Very little water will be required until the plants appear, and they should be watered sparingly till the leaves are formed and the pot begins to fill with roots. From the first keep them near to the light, as a short-jointed growth is always more fruitful and more easily managed than a spindly one. From 3-inch pots they are shifted into 6-inch, then into 8 or 9-inch pots; and these are quite large enough to produce the best early crops. We prefer using poor soil to induce dwarf growth and early fruiting, and supply with liquid manure freely after the fruit has formed.—K. G.

ROYAL HORTICULTURAL SOCIETY.

THE COMMITTEES.

THE arrangements for the year 1890 have already been announced, and the schedule is now issued, comprising the dates of meetings, Shows, and Conferences for the period named.

The following are the names of the members of the four principal Committees:—

SCIENTIFIC COMMITTEE.

Chairman.—Sir Joseph Dalton Hooker, K.C.S.I., M.D., C.B., F.R.S., The Camp, Sunningdale.

Vice-Chairmen.—W. T. Thiselton Dyer, C.M.G., F.R.S., Royal Gardens, Kew; Professor M. Foster, Sec. R.S., Great Shelford, Cambridge; Maxwell T. Masters, M.D., F.R.S., V.P.L.S., Mount Avenue, Ealing, W.

Hon. Secretary.—Rev. Prof. G. Henslow, M.A., F.L.S., F.G.S., Drayton House, Ealing.

Baker, J. G., F.R.S., Royal Gardens, Kew.
Blandford, W. H. F., M.A., F.E.S., 48, Wimpole Street, W.
Burbidge, F. W., F.L.S., Trinity College Gardens, Dublin.
Church, Professor A. H., F.R.S., Shelsley, Richmond.
Darwin, Francis, F.R.S., Wychfield, Huntingdon Road, Cambridge.
Dod, Rev. C. Wolley, Edge Hall, Malpas, Cheshire.
Elwes, H. J., F.L.S., F.Z.S., Preston House, Cirencester.
Frankland, E., F.R.S., The Yews, Reigate Hill, Reigate.
Gilbert, J. H., Ph.D., F.R.S., Harpenden, Herts.
Godman, F. Du Cane, F.R.S., 10, Chandos Street, Cavendish Square, W.
Llewelyn, Sir J. T. D., Bart., F.L.S., Penllergare, Swansea.
Lynch, R. Irwin, A.L.S., Botanic Gardens, Cambridge.
McLachlan, R., F.R.S., Westview, Clarendon Road, Lewisham, S.E.
Michael, Albert D., F.L.S., Cadogan Mansions, Sloane Square, S.W.
Müller, Hugo, Ph.D., F.R.S., 13, Park Square East, Regent's Park, N.W.
O'Brien, James, Harrow-on-the-Hill.
Oliver, F. W., D.Sc., F.L.S., Royal Gardens, Kew.
Pascoe, F. P., F.L.S., 1, Burlington Road, Westbourne Park, W.
Plowright, C. B., F.L.S., 7, King Street, King's Lynn.
Salvin, Osbert, F.R.S., Hawksfold, Fernhurst, Haslemere.
Scott, D. H., Ph.D., F.L.S., The Laurels, Bickley, Kent.
Symons, G. J., F.R.S., 62, Camden Square, N.W.
Veitch, H. J., F.L.S., Royal Exotic Nursery, King's Road, Chelsea, S.W.
Vines, Professor, F.R.S., Fairacres, Oxford.
Ward, Professor Marshall, F.R.S., The Laurels, Englefield Green, Staines.
Wilson, Geo. F., F.R.S., Heatherbank, Weybridge Heath.

FRUIT AND VEGETABLE COMMITTEE.

Chairman.—Sir Charles Strickland, Bart., Hildenley, Malton.

Vice-Chairmen.—T. Francis Rivers, Sawbridgeworth; John Lee, 78, Warwick Gardens, Kensington; R. D. Blackmore, Teddington.

Secretary.—Archibald F. Barron, Royal Horticultural Society, Chiswick, W.

Balderson, H., Corner Hall, Hemel Hempstead.
Barr, Peter, 12, King Street, Covent Garden, W.C.
Bates, W., Poulett Lodge Gardens, Twickenham.
Bennett, W., Rangemore Park Gardens, Burton-on-Trent.
Bunyard, George, The Nurseries, Maidstone.
Cheal, J., Crawley, Sussex.
Cliffe, G., Shoreham Place Gardens, Sevenoaks.
Coleman, W., Eastnor Castle Gardens, Ledbury.
Crowley Phillip, Waddon House, by Croydon.
Cummins, G. W., The Grange Gardens, Wallington.
Denning, W., Heathfield Nursery, Hampton.
Dunn, Malcolm, The Palace Gardens, Dalkeith, N.B.
Fairgrieve, P. W., The Palace Gardens, Dunkeld, N.B.
Ford, Sidney, The Gardens, Leonardslee, Horsham.
Hogg, R., LL.D., F.L.S., 99, St. George's Road, Pimlico.
Haycock, C., Goldings, Hertford.
Hudson, J., Gunnersbury House, Acton.
Lane, Fred, Berkhamstead.
McIndoe, James, Hutton Hall Gardens, Guisborough.
Moore, F., Blendon Hall Gardens, Bexley.
Moss, A., 39, London Bridge, E.C.

Norman, G., Hatfield House Gardens, Hatfield.
Pearson, A. H., The Nurseries, Chilwell, Notts.
Ross, Charles, The Gardens, Welford Park, Newbury.
Saltmarsh, T. J., The Nurseries, Chelmsford.
Smith, James, The Gardens, Mentmore, Leighton Buzzard.
Sutton, A. W., F.L.S., Reading.
Veitch, H. J., Royal Exotic Nurseries, Chelsea.
Veitch, P. C. M., The Royal Nurseries, Exeter.
Watkins, A., Exeter Street, Strand.
Warren, W., Worton Gardens, Isleworth.
Weir, Harrison, Sevenoaks.
Wildsmith, W., Heckfield Place, Winchfield.
Willard, Jesse, Holly Lodge Gardens, Highgate, N.
Wright, John, 171, Fleet Street.
Wythes, G., Syon House Gardens, Brentford.

FLORAL COMMITTEE.

Chairman.—William Marshall, Auchinraith, Bexley.

Vice-Chairmen.—J. Shirley Hibberd, 1, Priory Road, The Green, Kew; Maxwell T. Masters, M.D., F.R.S., V.P.L.S., Mount Avenue, Ealing, W.; Paul, George, The Old Nurseries, Cheshunt.

Secretary.—Archibald F. Barron, Royal Horticultural Society, Chiswick, W.

Baines, Thomas, Fern Cottage, Palmer's Green, N.
Barlow, S., Manchester.
Burbidge, F. W., Trinity College Botanic Garden, Dublin.
Blair, P. C., Trentham Gardens, Stoke-on-Trent.
Cannell, H., Swanley, Kent.
Castle, Lewis, Hotham House, Merton.
Dean, R., Raneagh Road, Ealing, W.
D'Ombra, Rev. H. H., Westwell Vicarage, Ashford, Kent.
Douglas, J., Great Gearies, Ilford.
Druery, C. T., 25, Windsor Road, Forest Gate.
Fraser, John, Lea Bridge Road, Leytonstone, E.
Girdlestone, T. W., Sunningdale, Berks.
Golding, W., 52, Gloucester Road, Kew.
Herbst, H., Kew Road, Richmond, Surrey.
Hill, E., Tring Park Gardens, Tring.
Holmes, W., Frampton Park Nurseries, Hackney, E.
Ingram, W., Belvoir Castle Gardens, Grantham.
James, J., Farnham Royal, Slough.
Jeffries, C., Boston House Gardens, Brentford.
Kelway, W., Langport, Somerset.
Leach, W. C., Aldbury Park Gardens, Guildford.
Lindsay, R., Botanic Gardens, Edinburgh.
Lowe, R. B., Ashbridge Gardens, Berkhamstead.
May, H. B., Dyson's Lane, Upper Edmonton.
Mawley, E., Rosebank, Berkhamstead.
Molyneux, E., Swanmore Park Gardens, Bishops Waltham.
Nicholson, G., Royal Gardens, Kew.
Noble, C., Sunningdale Nursery, Bagshot.
O'Brien, James, West Street, Harrow-on-the-Hill.
Pilcher, Charles, 84, Ringford Road, Wandsworth, S.W.
Pollett, H. M., Fernside, Bickley, Kent.
Ross, F., Pendell Court Gardens, Bletchingley.
Thomas, Owen, Chatsworth Gardens, Chesterfield.
Turner, H., Royal Nurseries, Slough.
Walker, J., Ham Green, Surrey.
Williams, W. H. (Keynes & Co.), Salisbury.
Wynne, B., 17, Catherine Street, Strand, W.C.

ORCHID COMMITTEE.

Chairman.—H. J. Veitch, F.L.S., Royal Exotic Nursery, Chelsea, S.W.

Vice-Chairmen.—J. Douglas, Great Gearies, Ilford; Maxwell T. Masters, M.D., F.L.S., Mount Avenue, Ealing, W.

Secretary.—James O'Brien, West Street, Harrow-on-the-Hill.

Baines, Thomas, Fern Cottage, Palmer's Green, N.
Ballantine, H., The Dell Gardens, Staines.
Castle, Lewis, Hotham House, Merton.
Crayshay, De Barri, Rosefield, Sevenoaks.
Cookson, Norman S., Oakwood, Wylam-on-Tyne.
Courtauld, Sydney, Bocking Place, Braintree.
Dominy, John, 11, Tadema Road, Chelsea, S.W.
Haywood, T. B., Woodhatch Lodge, Reigate.
Hill, E., Tring Park Gardens, Tring.
Latham, W. B., Botanic Gardens, Egbaston, Birmingham.
Lawrence, Sir Trevor, Bart., M.P., 57, Princes Gate, S.W.
Lindsay, R., Botanic Gardens, Edinburgh.
Moore, F., Blendon Hall Gardens, Bexley.
Philbrick, F. A., Q.C., Oldfield, Bickley Park.
Pilcher, Charles, 84, Ringford Road, Wandsworth, S.W.
Pollett, H. M., Fernside, Bickley, Kent.
Sander, F., St. Albans.
Schröder, Baron Henry, The Dell, Staines.
Smee, H. J., Wallington, Surrey.
Tautz, F. G., Studley House, Goldhawk Road, N.
Williams, H., Victoria Nurseries, Holloway, N.

PRUNING BUSH FRUITS.—In gardens where bullfinches and other small birds are troublesome, these clearing off the buds in a wholesale manner, it is unwise to do much pruning in the case of Gooseberries

especially before the spring. Red and Black Currants are not often greatly interfered with, and these may be pruned when perhaps it is too cold to proceed with the pruning and nailing of wall trees. Red and White Currants produce their fruit principally from the spurs formed on the old wood. All superfluous young wood should therefore be closely spurred back, and any required for laying the foundation of a bush or for extension ought to be shortened back to about one-third of their length, this being the only means of securing sturdy well-furnished main branches. Always keep the centre of both young and old bushes open, and do not crowd the main branches. Black Currants produce fruit throughout the entire length of young shoots formed during the previous season. These, therefore, should not be cut back, but only thinned out, as much of the old wood as possible being cleanly cut out at the same time. If the branches extend too far, or the centre of the bush is weak, foreshorten—that is to say, cut back the old wood with any young shoots attached to a well placed inner growth. Gooseberries may be pruned very similarly to Black Currants, but as fruit is freely produced by both young wood and spurs on old branches, the former may be much more freely cut out, or even all removed, abundance of fruit, birds and weather permitting, emanating from the closely spurred branches. In any case the low under branches should be cut out, fruit produced near the ground usually being dirty and worthless. Now is also a good time to remove old Raspberry canes, the young ones being thinned out and duly trained or secured in whatever manner may be in vogue.—W. T. M.

BIRDS AND FRUIT BUDS.

YOUR correspondent "T. A. C." (page 54) complains of bullfinches stripping a Beurre Clairgeau Pear tree of its buds, and inquires if others have had a similar experience. I have often known Pear buds to be attacked by these birds, and as recently as the past week I saw trees of Marie Louise that had been visited, and although the same havoc as spoken of by "T. A. C." had not been actually committed, the crops might have been seriously jeopardised had the birds followed their course unmolested. The ground was strewn with the outer scales of the fruit buds, and had the trees been of the orthodox bush or pyramid, instead of large orchard samples, the results would have been a thin crop indeed. In our garden last year a tree of Maréchal de la Cour, which always blooms early, was almost denuded of its fruit buds, but so far we have been spared from such mischief this year.

Sparrows sometimes prove troublesome among the Gooseberry bushes, especially in frosty weather when other food becomes scarce, and this year they have already given us some trouble, and not only will they devour Gooseberry, but Currant and Deutzia buds also. The latter is a new experience to me, but nevertheless a fact, for on taking in a portion of our stock to force, I observed that many of the buds had fared the same as those of fruit trees, and accordingly placed the remainder beyond the reach of the birds. "T. A. C." mentions Green Gages only, but I have not observed any partiality shown for these more than other sorts of Plums by the bullfinch. Indeed Damsons and Bullace trees I have seen completely stripped by them.

It is astonishing that birds so destructive should receive so much protection from owners of gardens, for I have been told that fruit shall be sacrificed rather than the birds should be destroyed. But these resolutions are mostly of winter's ruling, as is generally noticed, much to the discomfort of the gardener, disappointments are loud and long when summer arrives and brings with it no fruit. Allowance may be made for thrushes and blackbirds, for their delightful songs, which herald the spring, secure for them some favour even among gardeners, especially the thrush. I have always thought well of the starling as a useful bird to the gardener, and until within the last two years have never known them prove objectionable among fruit crops, but, like "T. A. C.," shall have to dissolve friendly partnership if they continue their unbounded partiality for Raspberries and Strawberries. If possible I believe them to be more greedy than even the blackbird or thrush among the before-mentioned fruits. The best antidote, in my opinion, is powder and shot, but it is not all who are allowed or who care to use them.—W. S., *Frome*.

YOUR correspondent "T. A. C.'s" (page 53) Pear buds seem to have escaped the ravages of these birds until this year. I am sorry to say I have found them as destructive on the Pear as on the Plum and other small fruit trees. This year they began their destructive work much earlier than usual. We have in an orchard a Pear tree 40 feet high of Maréchal de Cour, and for the last three years in succession we have gathered heavy crops of fine fruit. This variety is much prized at table for its splendid flavour and long keeping. The unwelcome intruders are attacking this tree with a vengeance. "F. B." says bullfinches are not insect destroyers except in breeding seasons, if so they are of little use. I, for one, would like to put an end to their existence within reach of fruit plantations. I have known them to attack Peach and Nectarine buds on the walls.—E. HAM, *Mountains, Hildenborough*.

THE WEATHER PLANT.

THE January issue of the "Kew Bulletin" devotes its twenty-eight pages entirely to a consideration of the Weather Plant, *Abrus precatorius*, concerning which so much has been written during the past year or two in metropolitan papers. Someone assigned the plant

the erroneous name of *Abrus peregrinus*, which went the round, and was accepted by many as the right one until it was authoritatively corrected. Mr. Nowack, an Austrian gentleman, seems to have investigated the subject carefully, and the Prince of Wales having introduced him to the authorities at Kew, a series of experiments was undertaken at Kew by Mr. Francis Oliver in conjunction with Mr. Nowack, the results of which are included in a number of comparative weather predictions and actual observations. In introducing the report the following remarks are interesting.

The plant, *Abrus precatorius*, *Linn.*, is a well-known tropical weed. Originally a native of India, it is now widely dispersed in tropical regions, including Mauritius, the West Indies, &c. It is a leguminous plant, with the habit of a shrubby climber. In the case of the plants used by Mr. Nowack, the young rapidly growing shoots were cut in before requiring any support. Thus the production of lateral shoots and foliage was stimulated. The seeds of *Abrus precatorius* are well known as "crab's eyes," and are used all over the world for decorative purposes. In India they are called rati, and are largely used by goldsmiths as weights, each weighing about $1\frac{3}{4}$ grain. It is stated that the famous Koh-i-noor diamond was first weighed by the rati, a word which is indeed supposed to have given origin to the jeweller's carat (*Kérat, Arab*). The powdered seeds are harmless when eaten, but rapidly produce fatal effects when introduced beneath the skin even in small quantity. They are used criminally in India in "Sui" poisoning, the object being to obtain the skins of the poisoned domestic animals. The poisonous action is due to the action of a proteid, *Abrin*. The leaves of the plant are 2 to 3 inches long, with ten to fifteen pairs of shortly stalked leaflets. The texture of the latter is very delicate and membranous; the surfaces glabrous.

At the point of insertion of each leaf on the stem is a slightly swollen joint or pulvinus, and each leaflet is provided with a similar small secondary pulvinus at its point of insertion on the main rachis. The rachis as well as the leaflets perform considerable movements both vertically and laterally on their pulvini. It is with these movements that the bulk of this report is concerned, as on them Mr. Nowack bases his various weather prophecies and harmonic charts. The leaves are arranged on the stem alternately with for the most part a divergence of half, but since on its development a leaf generally bends round through an angle varying from a few degrees to as much as 90°, it is found on an adult shoot that the leaves point in various directions. They spread themselves so as to obtain the most favourable illumination. This point is of some importance, and will be referred to later on.

I refrain from introducing histological details. But the mode of secondary increase in the thickness of the stem is peculiar and abnormal, as in many plants of climbing habit. The leaves, however, and the motile organs, the pulvini, do not differ in any character or manner from the same organs in other leguminous plants with motile leaves.

Some years ago seeds of this plant were communicated to Mr. Nowack with the statement that "they belonged to a wonderful flowering plant." He raised young plants from them, and was much impressed with the movements of the leaflets and of the leaves. That the movements in question did not depend on the immediate external conditions, Mr. Nowack soon satisfied himself. His observations suggested to him the existence of some connection between the movements and the state of the weather at a future period. The views which his further observations led him to adopt are contained in his pamphlet, published at Prag in 1888.

Mr. Nowack claims to be able to foretell, forty-eight hours ahead, the nature of the weather and its various changes, as well as the strength and direction of the wind, and rise or fall in temperature. Further, that intimation of the advent of earthquakes and of "Schlagwetter"—(i.e., escape of firedamp in coal mines) is given by the plants many days in advance. According to Mr. Nowack, individual plants of *Abrus precatorius* fall into two physiological groups; (1) the Weather Plants proper, which he speaks of as B-plants, and (2), plants indicating coming changes in temperature, T-plants.

I will now shortly describe the chief movements performed by these plants, and the significance attached to them by Mr. Nowack. In the first place, it is claimed that if plants of *Abrus* be allowed to grow undisturbed, the leaves as they develop will place themselves so that their axes lie in the chief planes of the compass N. and S., E. and W.—i.e., that all the leaves on a plant will point either N., S., E., or W. Further, if during its development a plant be turned through an angle, the leaves tend to move back to the four cardinal points. It is by noticing to which side of a plant any given leaf in a phase of movement belongs that the direction from which the indicated weather change will come is ascertained.

The leaves on any healthy plant fall into three categories, according to their age. The oldest leaves of all indicate weather for the immediate locality only, to the distance of half a mile. Leaves of an intermediate age, from five to ten miles; whilst the youngest leaves tell the weather for an outer zone to as great a distance as fifty miles. As the plant grows and develops fresh leaves, those which were a short time before the youngest, and which told the weather for the distant zone, gradually pass over to the intermediate category, and indicate for the middle zone, and finally only for the immediate locality. It must be remembered, then, that the leaves of different ages are sensitive to changes in the weather at varying distances from the point at which observations are being made. The manner in which these changes are indicated is the same in all cases. Thus, a thunderstorm to occur at the greatest distance is signalled forty-eight hours beforehand by the

youngest leaves only; one for the immediate locality is in the same way indicated by the oldest leaves.

From a hurried glance through the tables it appears that the predictions are practically valueless, as though occasionally corresponding in some degree with the weather which actually occurred, in a great many cases there is a wide divergence, as, for instance, the prediction for October 7th at 9.30 A.M. was "overcast," at 10.30 A.M. "fair to fine," the records for the same times showing "fine" and "heavy shower."

FRUIT FORCING.

PEACHES AND NECTARINES.—*Earliest Forced Trees.*—Continue to fertilise the blossoms, using a camel's hair brush or feather, which is more effectual than shaking the trellis. When the fruit is well set, syringing may be resorted to, in the morning and afternoon, but in dull weather syringing in the morning will be sufficient, damping the house in the afternoon, it being important that the foliage be dry before night. The water employed must be of the same temperature as that of the house, the inside border receiving liberal supplies. Disbudding will soon require attention, but it must be done carefully at this early season, as it is better to remove a few shoots daily from a tree than many at a time at distant intervals, thus giving a check to the roots. The night temperature may now be maintained at 55° to 60°, 60° to 65° by day, 5° less as the minimum when the weather is severe and dull, admitting a little air at 65°, not allowing an advance over 70° without full ventilation, closing at 65°, except a small space left at the top constantly.

Second Early Forced Trees.—Syringing must cease for trees started at the beginning of the month when the flowers show colour, but damping every available surface in the morning and afternoon must be practised, for though a confined atmosphere is not favourable to Peaches in any stage of their growth, a dry atmosphere is equally pernicious, promoting excessive evaporation, the flowers equally with foliage and fruit being invigorated by atmospheric moisture, provided it is not stagnant. See that the border is in a thoroughly moist state, and examine the trees closely for aphides. If there be any, fumigate the house on two or three consecutive evenings moderately, which will be sufficient to keep the pests under until the fruit is set. In case of an excess of flower buds (and they are very abundant and promising) draw the hand the reverse way of the growth along the under side of the trellis, so as to reduce the number of the buds, which will increase the vigour of those best situated, and tend to a more even and better swelling of the fruit after setting.

Late Houses.—We should again urge the necessity of completing the pruning of the trees at once, dressing them with an insecticide, and tying the shoots to the trellis, the borders being forked over, but not disturbing the roots, any loose surface soil removed and fresh loam supplied, an admixture of wood ashes a fifteenth part, and a twentieth of half-inch bones, being beneficial. If the borders are at all dry they should be given a thorough soaking either with water or liquid manure. Those, however, that have moveable roof lights will not require any water, the soil being in a healthy condition—a thoroughly moist state from rain, and the shoots are kept in a condition by the air moisture unfavourable to the operation, so that the trees not only have thorough rest, but the buds are prevented falling, a consequence mostly of deficiency of moisture at the roots. With the trees exposed we have not experienced any loss of buds, yet they may fall from other causes, such as over-maturity or imperfect formation through attacks of parasites and deficiency of aliment and assimilating power, resulting from too crowded a condition of the foliage.

PINES.—*Fruiting Plants and Starters.*—Those should now have a mean temperature of about 70°, varying it 5° according to external conditions, admitting air at 80° with sunshine, but not lowering the temperature, allowing the heat to rise to 85°, closing when reduced to 80°. Syringe all available surfaces twice every day, but do not syringe the surface of the bed between the plants. Avoid dense steam produced by damping highly heated pipes. The plants also should be syringed occasionally early in the afternoon when the axils of the leaves become dry.

Starting Plants for Successional Fruiting.—About the commencement of next month (February) start another supply of Queens to supplement the fruit from those which are already introduced. Beds having hot-water pipes beneath them can soon be prepared for the reception of the plants, but it is not the case where fermenting materials alone are employed, hence the subject is mentioned now, so that the matter may be seen to at once, and 85° to 90° of bottom heat secured by the time required. When plants which have been kept somewhat drier are to be started see that the soil is made thoroughly moist, so that with the extra warmth root action may commence at once.

Successional Plants.—A night temperature of 60° to 65°, and 5° less in severe weather, will be suitable for those, and 5° to 10° in the day-time according to external conditions. Keep the plants rather dry at the roots, but not excessively so, and when water is considered necessary give it thoroughly at a temperature of about 80°. Suckers should have

a temperature of 55° to 60°, 60° to 65° by day from fire heat, and 10° more with sun heat.

CUCUMBERS.—The night temperature should be maintained at 65°, allowing 5° more in mild weather, whilst it may be 5° less on cold nights, 70° to 75° by day, and 80° to 85° with sun heat. When the external air is mild a little ventilation may be given at 80°, closing before the temperature is reduced below that degree, so as to raise it to 90° or 95°; but if the external air is cold, although the sun shines, it is better to allow the temperature to advance a little beyond the above limits than to admit cold air, which injures the foliage, also causing the fruit to become stunted and to curl at the end. Plants in bearing will require to be examined about twice a week, removing all weakly and exhausted growths, reserving as much of the young bearing wood as is necessary to fill the allotted space, stopping the shoots at one or two joints beyond the fruit. Young plants just coming into bearing should not be allowed to bear too soon, and by no means be overcropped. They are greatly assisted by removing the male flowers (also surplus female flowers) as they appear. The supply of water both at the roots and in the atmosphere must be governed by external influences. Do not syringe the foliage except in the early part of bright afternoons, damp the floor moderately at about 8 A.M. and 2 P.M. Encourage the roots to spread on the surface of the bed by adding a little lumpy loam from time to time, with which may be incorporated a little well decomposed cow dung or fresh, sweetened, horse droppings. Keep a sharp look out for aphides, and fumigate several times moderately and consecutively rather than once severely. Canker is not uncommon at this season of the year. Fresh slaked lime rubbed into the affected parts will arrest its progress. If mildew appear dust with sulphur.

MELONS.—Add a little soil as a top dressing as the plants grow, having them near the glass to prevent drawing. Keep a sharp look out for slugs. A ring of soot or lime placed round the plants will generally preserve them, but means should be employed to entrap the slugs. For frame culture seed may be sown early next month. Soil should be placed under cover, so as to become dried preparatory to forming it into ridges in the Melon house. Good loam, rather strong than light, is suitable for Melons, and if it has been laid up in ridges so as to reduce the turf, it will be in a fitting state for the purpose. If deficient of grit, add a fifth of road sweepings, and if not calcareous a similar proportion of old mortar rubbish. If there is need to add manure, nothing is better than fresh horse droppings. The composition in that case would be four parts of loam, one part each of horse droppings, road sweepings, and lime rubbish.

Raising Cucumber and Melon Plants in Frames.—It is the greatest of mistakes to commence too early. The materials are either not obtainable, or they are not forthcoming in sufficient quantity to make up beds and continue the heat in them by linings, so as to keep the plants in progressive growth during weather that cannot be relied upon as assisting by sun heat, consequently those not sowing seed before February cut fruit quite as early as some do with an inadequacy of heat furnishing material by sowing at the new year. The material for making up the bed for raising the seedlings being in a fit state for turning over and mixing with leaves, so as to induce a sweet regular heat, a site for a bed should be chosen with full southern aspect, and having shelter to the north, as that of a wall or hedge. If the ground be rather higher where the bed is to be formed than the surrounding ground, all the better. Beat the dung and leaves well down with a fork as the work proceeds, making the bed about 5 feet high at the back and 4 feet 6 inches in front, which will allow for settling, as it will do about a third. A few pea sticks placed across the bed at intervals not only prevent overheating, but admit the heat from the linings to the interior of the bed. For early work we have used and frequently recommended frames with double sides. They are formed by placing an inner lining of half-inch boards, 9 inches less in depth at the back and 6 inches less in front than the box, nailing strips of wood an inch wide and thick on the inside of the box, and then the boards which form an inch cavity all around the inside of the box, and thus top heat is furnished.

In about a week the heat will be up. Level the surface of the bed, replace the box, and put in sufficient sweetened dung to raise the inside to within 4 inches of the top of the inner frame or cavity, placing sawdust, dry leaf soil, or spent tan on the dung for plunging the pots in. For raising the plants 3-inch pots are half filled with light rich loam, placing one seed in the centre of each pot, covering with fine moist soil, so that no water is required for the germination of the seed. Space is thus left in the pot for top-dressing, which is preferable to potting the plants. A square of glass placed over the pots will hasten the germination, but it must be removed as soon as the plants appear. Those from a sowing made early in February in the manner described will be ready for planting early in March, and will afford fruit nearly as soon and often quite as early as those from a sowing made early in January.

HINTS FOR BEGINNERS.

EARLY FEEDING AND ENEMIES.

Owing to the extra mild season we have had the bees have never been more than a few days confined at a time, not a week

has passed without some of them being on the wing. Carniolians are as usual the most quiet, but on January 1st young bees were playing on the alighting board of one of them. The blue tits were very busy for a time in picking up any dead ones thrown out of the hive, but owing to my bees being nearly all wintered in full sized deep hives they fail by their pecking at the doorway to induce the bees to respond, so from them and other flying enemies they are comparatively safe. Owing to the position of my hives, and their construction, mice, which are very destructive to bees, cannot enter. To prevent these troublesome pests gaining an entrance, Mr. Wm. Hogg uses queen-excluder perforated zinc on the doorways. The zinc is first cut two holes broad, then the under row is again cut so that the height is the full size of the original doorway of the hive, which gives the bees a tolerably free entrance, where it is absolutely necessary to contract it if mice are numerous. The lowest temperature upon three different nights was 20° Fahr., being 12° below the freezing point; consequently bees that have been breeding and flying late will have consumed much honey, and probably be anticipating an early spring. Flowers have never been absent with us, and the spring ones are pushing forward rapidly. Hives will make similar progress. It will therefore be wise to feed the bees at once, or rather on the first day after they have well aired themselves during the present month. Neglect of this will result in an entire loss of all hives that were in want, and which a few pounds of sugar timely given would have saved and probably made profitable.

THE FEEDER.

As there are so many feeders in the market, every one being held up as perfect, it may be advisable to instruct the beginner how and when to feed. The thoughtful bee-keeper will discontinue feeding bees between about September or the beginning of October, leaving the bees with as much as will tide them over till April or May. Feed earlier in exceptional cases only, and always when necessary take advantage of January mildness, which for half a century now I have never known to be absent. It is best when the hive is large enough to contain stores sufficient for the bees till midsummer, but when this is not the case great attention should be paid to all hives that none linger or go back during April or May, or even June; when this occurs it puts an end to all profit from the June and July gathering. Early swarms are greatly benefited by feeding gently for a week or so after being hived, or as long as honey does not come in. Avoid too rapid feeding. If combs are to be made the bees are inclined to swell them irregularly, and they often collapse. The bees become gorged, are unable to defend themselves, and often when in this state fall a prey to robber bees. From 2 to 4 lbs. every twenty-four hours is ample for any hive; too rapid feeding wears out the bees and overheats, and starts incipient foul brood. There should be a feeder for every hive, so that there will be no risk whatever of inflicting stocks that may be fed from a feeder that had been used by an infected stock.

Feeders should be of wood as much as possible where the bees come into contact with them, and the syrup is so placed that the bees will not have far to travel from the combs to get it. Float feeders, unless it is merely to cover the tin of shallow feeders, cannot be recommended, and the slow stimulative feeders are but toys, and I believe does more harm to bees than good. I use the "universal feeder," partly described at page 564 last December. It consists of a tin $4\frac{1}{2}$ inches square and holds about 2 lbs. dissolved sugar, with or without a pane of glass. The neck should be neat, half an inch long over all, which has a brass screw, such as is used for oil cans, not more than seven-eighths of an inch outside measure soldered to it. A hole about a quarter of an inch is drilled in the centre, receives the valve, which is a broad-headed saw handle screw nail, which I omitted to state at page 564. It is absolutely necessary these sizes should be adhered to

The next thing in connection with this tin is the feeder proper.

It is simply a frame having a top bar $1\frac{1}{8}$ of an inch thick instead of half inch. To make this feeder dress a piece of wood the exact length of the top bar, $1\frac{3}{4}$ inch broad by $1\frac{1}{8}$ inch thick. Now mark off 2 inches in the centre of top bar and $1\frac{1}{4}$ at each end, which must be kept entire. Bore an inch hole five-eighths of an inch deep; this is to receive a neck of tin, at the extreme of the centre 2 inches, and at the extreme of the end $1\frac{1}{4}$ inch make a saw cut one-eighth of an inch deep, bevelled inwards so as to hold a pane of glass, then make other cuts fully an eighth of an inch inside those first cut, but square and three-eighths down. Now cut out this neatly, and when done clean away the wood to the first cut an eighth down; this will now be ready to take the glass, which is slipped in edge-ways, the bevelled wood preventing it falling out when inverted. As yet there is no way for the bees to pass up to the syrup, but by continuing the saw cut down the edges one-quarter deep, this cleaned out leaves the frame inside the ends and centre piece $1\frac{1}{4}$ broad. Trench a trough three-eighths of an inch deep in centre of bar, and drill a hole between the inch hole in the centre and the trough, so that the syrup flows into the trough when the tin is inverted, and the valve touches the bottom. This trough gives about 2 feet standing space for bees to feed, and will take 2 lbs. of sugar in less than two hours when in a feeding state. No feeder can possibly excel this one as a top feeder; it not only can be used for syrup, but one of the troughs may be set apart for pease brose made with honey. In this form I have fed my bees for nearly forty years.

If you wish to render the feeder still more serviceable a trough for placing on the top of the frames is used; it is made from wood about 6 inches square by five-eighths thick, half an inch from one edge, the trough three-eighths wide and deep is cut, and a trench is cut behind communicating with the trough, three-eighths of an inch is raised round the trench to fit the neck of the tin, and a casing is all round the feeder. A pane of glass slides in a groove over the trough and the bees ascend to it. A small queens' cage fits into this, and queen introduction and feeding continue at the same time, which I have found satisfactory. As an under feeder with a tin scoop about $1\frac{1}{2}$ inch broad by three-eighths deep, having a bit of spale as a float when feeding at the front, but when fed from behind beneath the perforated zinc floor is of no use. This latter plan is the best place to feed when it is necessary to do so when the hive is covered up, and when the bees are likely to be flying as when at the moors. Altogether the bees can be fed six different ways with this feeder, and stranger bees cannot get at the syrup without having to pass through the hive or the sentinel bees, while the fountain may be left out full of syrup no bee can gain an entrance to it. The fountain and scoop should not cost more than 1s. each, while every bee-keeper can make easily enough the frame and box feeder.—A LANARKSHIRE BEE-KEEPER.

(To be continued.)

BEEES HYBERNATING—REARING QUEENS.

In the Journal for the 9th "A Lanarkshire Bee-keeper" takes exception to some parts of my article. He questions whether bees hibernate, I can inform him that out of twenty-six stocks of mine all but two are truly hibernating. They are located on a hillside sloping due south at an angle of about 30°, and are thus well sheltered on the north, also by high buildings on the west, so that when the sun shines it is quite warm, even in winter. On Sunday, the 12th, the temperature rose in the shade to 65° after a very windy morning, so with the sun in full height about 1 P.M. I thought I would note how many had "woke up." It was so warm and bright that I expected every one would be in flight, but only six stocks showed bees flying, with one only in full flight, a stock of Cyprians, which looked truly beautiful in the sun.

I cannot expect, or hope, to convert all at once, but let bee-keepers rear their queens on the lines I have laid down for three or four years they will believe then, I think, and he will be a bold man to assert that my plan is worse than any other. "A. L. B. K." admits the bee-keeper will be a gainer, though he thinks, like many others, that his methods are satisfactory. I do not question his statement at all on this. What I want is progress. The things that were satisfactory in bygone times will not do in these days, nor will those of to-day do in the future.—A HALLAMSHIRE BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

Little & Ballantyne, Carlisle.—*List of Flower and Vegetable Seeds, 1890.*

M. de Reydellet, Valence (Drôme), France.—*Catalogue of Chrysanthemums.*

F. C. Heinemann, Erfurt.—*Seed Catalogue, 1890.*

T. S. Ware, Tottenham.—*Catalogue of Flower Seeds, Chrysanthemums, Dahlias, and Gladioli, 1890.*

W. Piercy, 89, West Road, Forest Hill, S.E.; Dobie & Mason, 66, Deansgate, Manchester.—*List of Reliable Seeds, 1890.*

Samuel Yates, 78, Shadehill, Manchester.—*Catalogue of Seeds, 1890.*

William Eull, 536, King's Road, Chelsea.—*Catalogue of Flower and Vegetable Seeds.*

William Baylor Hartland.—*Year Book of Seeds, 1890.*

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Vine Shoots and Vine Wood (X. J. Z.).—Please send particulars of the age and condition of the trees and border, and indicate the treatment that has been pursued at the roots and otherwise; also favour with similar information about the Vines from which you send wood, and state the extent of the cropping in both cases. It is necessary that we receive the information this week for a satisfactory reply being inserted in our next issue.

Cyclamen (J. C. G.).—The flower and leaf of Cyclamen having been sent in a dry box, without any packing, such as green leaves or grass, arrived completely withered and curled up, so that no estimate could be formed of the merits of the variety. The photograph you send represents an admirably grown plant, which you say measures 2 feet 7 inches across, and on a day which you mention was bearing 226 flowers. The specimen is most creditable to the cultivator.

Palms for the Isle of Man (A. D. Doug'as).—You might try *Chamaerops Fortunei*, which would be the most likely to succeed. Possibly in sheltered places *Phoenix dactylifera* would be safe, at least it can, with many others, be grown out of doors in the summer. In the *Kew Bulletin* for December last you will find much useful information respecting the Palms grown in the Riviera. It can be obtained through booksellers or from Eyre & Spottiswoode, East Harding Street, Fleet Street, E.C., price 2d.

Fruit Trees in Pots (A. B.).—Under the circumstances you describe we should have removed the trees from the house some time ago, and packed litter round and over the pots, and thatched this to prevent the heavy rains we think you have in your district saturating the soil. If the buds are still dormant we should remove the trees now, and shelter them as you propose in severe weather. If you retard the flowering you may expect a better set of fruit under favourable atmospheric influences under glass.

Peach Trees Unsatisfactory (Idem).—In your case there can be little doubt that the premature falling of the buds is the result of immature wood. You would probably have done well by again lifting the trees before the leaves fell last autumn. Your object should be to encourage a mass of fibrous roots near the surface in firm calcareous soil, then by disposing the growths thinly the wood would have the best chance of ripening. You had better carry out your proposition of employing more fire heat, so that more air can be admitted and a drier atmosphere maintained, especially in the autumn. Fire heat is often of great benefit in the daytime after the fruit is gathered, and until the leaves change, with full ventilation. All the wood not required for the next crop should be cut out as soon as possible in the autumn after the fruit is removed from the trees. More than half the Peach trees in the kingdom are much overcrowded in the summer and autumn by retaining too many shoots when disbudding, and letting them remain till the leaves fall. You say your "place is white with Snowdrops and Winter Aconites." We suspect you mean white and yellow. If you have any white Winter Aconites we shall be glad to see a few of the flowers.

Tabernaemontana Flowers Falling (W. W.).—Are you sure the soil has not become too dry at some time during the past month? An hour's dryness would cause the buds to fall, so also would a sudden change from a moist to a dry atmosphere; and if you syringed freely and frequently you may have gone from one extreme of moisture to the other by ceasing syringing altogether. Then, again, a sudden fall in temperature would prevent the flowers expanding. Try a night temperature of 65°.

Ventilating Three-quarter Span-roofed House (S. G. R.).—The house will be efficiently ventilated by having a board or flap ventilator 11 inches wide the whole length of the front, and is best either immediately below the sill or roof plate, or immediately above the intended inside ground level. It will answer very well as shown in your sketch. The top ventilation is best on the south side of the roof, the lights being 2 feet deep and the whole length of the house opening with crank and lever movement so as to facilitate operations.

Annuals for Cutting (J. B.).—In addition to those mentioned in your letter the following are grown for the purpose in question:—Sweet Peas, Cornflowers, *Acrocliniums*, *Rhodanthes*, *Nigellas*, *Mignonette* in varieties, *Venus's Looking Glass*, *Erysimums*, *Phlox Drummondii*, *Larkspurs*, *Dwarf Convolvulus*, *Godetias*, *Helichrysums*, *Bartonia aurea*. We should not consider it the best plan to sow these and some of those you name in hotbeds in February and transplant them twice as you describe. You, however, cannot do better than follow the practice you have found successful. We should sow several outside towards the end of March or in April for succession, thinning the plants early and sufficiently, and allow them to grow and flower without any transplanting.

Moss on Lawn (G. B.).—Your lawn probably needs draining. There is no permanent cure for moss in lawns when the soil contains stagnant water. It is not at all uncommon for soot to do good on many lawns, then in two or three years for the moss to grow as luxuriantly as ever. On a suitable day scratch out all the moss you can with a small fine-toothed rake, then spread on the surface a mixture of equal parts of wood ashes, lime, and soil (sifted) nearly a quarter of an inch thick if you have enough. Do this now, and in about a month's time sow a renovating mixture containing White Clover seed, scratching it in, also sifting a little fresh soil over it, and draw a light clean roller over the surface. If this fails to accomplish the desired object, nothing will do so except draining.

Fuchsias for Cutting (Subscriber).—We presume from your letter that you refer to varieties usually grown in greenhouses, that you desire to plant outdoors in summer, and take up in the autumn for preserving through the winter. This we have done for years, and the older the plants became the more satisfactory we found them. For the purpose in question we have found the old Rose of Castille one of the most useful, but a newer variety, Prince Alfred, is equally free, and has a darker corolla. *Erecta Von Novelty* is also good for your purpose. Those have white sepals. A good variety with white corolla is *Flocon de Neige*. Suitable dark varieties are less numerous. One of the best we have seen for vase decoration is *Madame Thibaut*; *Crimson Globe* is also good. You should plant some of the hardy border Fuchsias, and allow them to remain to be cut down by frost, as they will be in your district, and grow again in the spring. The most useful of these we have found in *F. Riccartoni*, though *F. corallina*, *F. coccinea*, *F. gracilis*, and *F. discolor* are worth growing for affording sprays for cutting.

Vinery Arrangements (J. G.).—The width being 22 feet, the height from the floor level in the centre of the house may be 13 feet as you propose—certainly not less than 11 feet. 1, A flow and return 4-inch pipe all round the house, except doorway, will give sufficient heat, the house not being intended for forcing. 2, It is no disadvantage to have the Vine border inside, the only difference is that an inside border entails more labour in watering; the roots being inside are under control, and can be fed by surface dressings or liquid manure as required. As there is water at 3 feet depth it would be well to have drains to carry it off, at least there must be a drain with proper fall and outlet to take superfluous water away from the drainage, as Vines cannot be satisfactory in a water-logged border. In other respects your proposed method of forming the border is sound. If the border is made 4 feet wide and the old soil left in the unmade part it will not be necessary to put anything down to keep the roots from entering the unmade part, as the few the Vines make in it will not prejudice their growth when the other part of the border is made, through their being disturbed. The house being 20 feet long five Vines on each side will be a proper number. Half the Vines being Black Hamburgs, you may have Foster's Seedling, Madresfield Court, Alnwick Seedling, Mrs. Pearson, and Lady Downe's. The Vines being started early in March the Black Hamburg will be ripe late in July or early in August, and the others will ripen successively afterwards—all by the middle or close of September, and afford a supply of Grapes up to the time of again starting the Vines, or later; but the Grapes must be cut and bottled not later than the new year, so as to allow of the Vines being pruned, and have a few weeks' rest. The best Vines to plant are those known as "planting" canes, which are usually one year old from the eye, being clean, healthy and well rooted.

Pear not Bearing (J. F. W.).—As you say the tree was "thoroughly root-pruned two years ago," and your gardener thinks it does not make too much wood, it is a little strange it does not produce flower buds on a wall facing west. Possibly it may do so this spring, as last summer was much more favourable for ripening the wood than the

season of 1888 was. Blossom buds can be distinguished from wood buds now on careful examination. Are the main branches too close together? They should be sufficiently distant for a little of the wall to be seen between them when the tree is in full leaf in the summer. Many trees are prevented bearing by overcrowding of the growths and foliage. If you had stated the length of the summer shoots or breast-wood we could have formed our own opinion as to whether that is excessive or not. On many trees not only are the branches too close, but the spurs are too near together on them, and we have seen excellent results follow through some of them being cut out. Also when Pear trees refuse to form fruit buds under ordinary spur pruning, we have seen them rendered fruitful by cutting out some of the branches, and so affording space for training selected summer growths their whole length, and where the leaves were not shaded in the least by the growths from contiguous branches. On such unshortened young wood fruit buds form naturally if the trees have sufficient fibrous roots in good and firm soil. Digging and cropping to within 2 or 3 feet of the stems of fruit trees is not conducive to fruitfulness. We should hesitate before destroying a healthy tree of such a good Pear as Doyenné du Comice. This variety bears us good crops of excellent fruit. If you like to give more particulars of the tree, and briefly describe the method of summer and winter pruning that has been pursued, enclosing a rough sketch if practicable, your letter shall have attention. We much prefer returning to a subject when we can do so usefully than dismissing it summarily, if additional information can be supplied.

A Too Successful Prizewinner (Head Gardener).—The proposal you submit is a novel one, and we print the substance of your letter in case any of our readers can aid in solving the problem. Here it is:—"An exhibitor last year took away all the best prizes at our local show, which caused a feeling of jealousy amongst the cottagers. Our Committee are desirous of preventing a recurrence at the next show, and proposed to introduce a new rule as follows:—'No exhibitor shall be allowed to receive more than three first prizes.' Now comes a difficulty. The Judges will in all probability award many more than three first prizes to one exhibitor, as was done last year; but having the above rule against them their decisions are to be set aside at the time the prizes are paid to the winner, by only giving him the three first prizes as above stated, and should the Judges have awarded him more the winner is to be informed he is not entitled to them under the new rule, and must give them up to a second prize winner in the same class, and he (the first prize winner) take the seconds. I am inclined to think the above will cause a great dispute, but should be glad to have your opinion." Our opinion is the same as yours—namely, that a "great dispute" will arise if the project is carried out, and it will not be surprising if a successful exhibitor, who is fully entitled to compete in the classes, finds many friends who will dissent from the treatment indicated. A person is either eligible to compete, or he is not. If he is, and the Judges award him a first prize in every class, he is entitled to those prizes. They are the rewards for excellence. If a number of these prizes were taken from him and given to exhibitors of inferior produce, this would be according honours to which the second prize men had no just claim. When the Committee can prove that two wrongs make a right, it will be soon enough, in our opinion, to adopt the curious proposal. If a striving man wins so many more prizes than his fellow competitors, it is for them to bestir themselves and defeat him honourably, and if they cannot do so to submit manfully. That is our view of the case, and if those of our correspondents who have had to encounter difficulties in the management of cottagers' shows can tell you how to proceed in surmounting yours, they are at liberty to do so.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (C. G.).—The Apple resembles Sweeny Nonpareil, but the fruit is imperfect; no one could name it with certainty. (J. B.).—The seedling Apple is worthless; we should cut the tree down and insert scions of a known good variety.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (W. G.).—You think there was a "mistake somewhere," but state no reasons for the assumption. Perhaps you made a mistake in the numbers. We have no doubt the specimens were correctly named.

MANURE FOR GRASS LAND.

MOISTURE and heat for the growth, fine weather for the harvest, and an ample store of fertility in the soil, are the chief factors to success in a crop of hay. We cannot command fine weather, but we can ensure an early vigorous growth by the timely and judicious use of manure. Careful experiments of the various fertilisers known to us have been tried on the land in different parts of England and Scotland, and the results show uniformity in one point only—i.e., that it is impossible to fix the exact quantity per acre of any manure for general use, or even for particular localities. Some results are positively misleading, as for example in the recent report of the Dyson Wood experiments, we are told that one of the plots dressed with 3 cwt. dissolved bones at a cost of 18s. per acre yielded 38 cwt. $1\frac{1}{2}$ qr. of hay. Now here the cost and the results are alike tempting; but anyone who has had practical experience of such manures must know that interesting and valuable as this experiment is when taken in comparison with the others at Dyson Wood, yet it is worthless for general adoption. No doubt dissolved bones are a particularly safe form of manure for general use, but pasture, like animals, thrives best on mixed food, and the mixture can be had for very little more than the cost of the dissolved bones.

When really genuine pure manures are used we have found that 3 cwt. per acre is an ample dressing if applied every year in February. Pray mark this, for though it is easy to talk about "strong" land and rich soil, yet there is no such thing as a permanent storage of any soil with fertility. Every crop taken from the land is more or less exhaustive, and if we would ensure the next crop being a full one manure must be used. Having thus once more made clear the necessity and importance of periodical manure dressings, let us now see of what our grass manure mixture should consist to render it sure and safe for general use. We require a well-balanced mixture of mineral and nitrogenous manure, in which nitrogen, potash, and phosphoric acid (the essential elements of plant food), are all present in sufficient quantities to ensure a full crop in any soil. We take, therefore, as our chief ingredients 1 cwt. nitrate of soda and $1\frac{1}{2}$ cwt. mineral superphosphate, and add as auxiliaries to render it a complete manure, $\frac{1}{4}$ cwt. muriate of potash, and $\frac{1}{4}$ cwt. steamed bone flour. Taken at ton rates this manure can be had put on rail at about 20s. per acre, to which there would be some additional outlay for carriage, mixing, and using, for the manures should always be had separately and mixed at the farm under careful supervision. The best way to apply it is with an Excelsior drill, which makes a capital broadcast sower when the coulters are taken off, and the sowing can be regulated to a nicety, and checked by the dial plate on the drill. Nitrate of soda always contains many large portions which must be pulverised by a sharp stroke or two with the back of a shovel. We have always found this sufficient without sifting when the manure is sown broadcast. Sifting is only necessary when the manure is drilled with seed, as it is then liable to clog the coulters if not quite fine, and it should not be forgotten that manure merchants charge 5s. per ton extra for sifting.

We strongly urge all managers of home farms to use the mixture we recommend for pasture and forage crops this spring, only take care that the manure is pure, and that it is used early, and we are confident the result will be entirely satisfactory. It is because we have used it largely on light, mixed, and heavy land on various formations in different counties with singularly uniform success that we are able to speak with such confidence about it. Many tenant farmers have used it under our guidance, and their outspoken expressions of gratitude on finding the results were much beyond their expectations were assuredly pleasant hearing. It is only by actual demonstration that we can hope to inspire men of this class with the confidence necessary to ensure a free use of pure chemical manures. Many landlords have subscribed liberally to associations formed for the improvement of agriculture, they have also done much for tenants by reduction and remission of rent; but they can do more by having pure manures used at their home farms and at any farms falling in hand, and they would enable tenants to help themselves if assistance were given him in the welcome guise of enough manure for his pasture this year, on condition that it should be used under the supervision of the landlord's agent. No doubt to procure each sort of manure separately and to have the mixing done at the farm involve some labour, but it is certainly labour well bestowed, and it is high time that farmers ceased to waste their means upon doubtful mixtures into which dustbin refuse enters so largely.

WORK ON THE HOME FARM.

Work on the land has been slack, and there has been time to examine, clean and repair implements and tools. The worn tines and hoes of cultivators and harrows have been repaired, broken chains mended and worn links renewed; wheels and rollers have been greased, and all wood and iron work on carriages and implements has been painted. The advantage of all this when the busy time of spring comes round again is so obvious that any reminder of it would appear unnecessary, but it is unfortunately exceptional to see a farming plant kept in good order. Tools and implements in good order tend to help on work briskly, and often enable one to be beforehand with work. It is a good rule to have every implement brought to the homestead upon the completion of every special job, and never to allow ploughs, harrows, rollers or cultivators to be left by hedge or ditch till they are wanted again. Mowing, reaping and binding machines should also be over-

hauled, all worn bearings repaired and gearing made quite sound and strong. Horse rakes and tedding machines with bent or twisted teeth are a hindrance to work, and should be set right now, and it may make several days' difference to our advantage when they are wanted. We had occasion to call on a large implement maker just as haymaking had begun last season, and found quite a crowd of old mowing machines that had been sent in for repair just as they were wanted for work, and orders for new tedding machines were coming in faster than they could be supplied. Moral: Get your repairs done and what new implements you require now, and then not an hour will be lost when you require them for use.

The mild open weather is most favourable for early lambs, and they are doing well. Shepherds must be on their guard against any sudden change to colder weather, and keep the lambs near the fold or other place of shelter. See that plenty of fresh dry litter is used in the fold, and get ewes and lambs out on the pasture on all fine days. With the fine stock of hay the temptation to use it freely will be great, but it is always well to have an ample store of old hay, and with plenty of good sweet chaff, grass and roots very little else is required. Silage now takes the place of hay both for sheep and cattle. It is a nourishing article of diet, and is in every way a boon to the farmer.

A FIELD LAID DOWN TO PERMANENT GRASS.—A paper, by Sir J. B. Lawes, on the history of a field laid down to permanent Grass, has been reprinted, by Messrs. Spottiswoode, from the Journal of the Royal Agricultural Society of England. The field in question forms part of the Rothamsted estate, and was laid down to permanent Grass nearly thirty years ago by Dr. Gilbert, to whom it was left in 1856. It has been mown for hay every year from the commencement; and in the present pamphlet Sir J. B. Lawes gives full particulars as to the economical results, the constituents supplied in the manures and removed in the crops, the changes within the soil in the formation of the meadow, and the botany of the meadow. The following are his summary and general conclusions:—(1) By the judicious employment of manures, both natural and artificial, arable land has been converted into permanent Grass, not only without loss, but with some profit to the tenant. (2) The important constituents, nitrogen and phosphoric acid, were supplied in the manures in larger quantities than they were removed in the crops; but potash in only about the same quantity as it was removed. (3) The application of dung not only compensates for much of the exhaustion from the removal of hay, but it has a beneficial influence on the botanical character of the herbage. (4) Although the Grass has been mown every year for nearly thirty years, there has been a considerable accumulation of fertility within the soil. (5) Analysis has shown that there has been an increase of nitrogen in the surface soil, beyond that which could be explained by excess supplied in manure over that removed in crops, and by the combined nitrogen coming down in rain, and the minor deposits from the atmosphere. Part, if not the whole, of this increase is probably derived from the subsoil by deeply rooted plants, which afterwards leave a nitrogenous residue within the surface soil. Or, possibly, some of it may have its source in the free nitrogen of the atmosphere, brought into combination within the soil, under the influence of micro-organisms, or other low forms. (6) In laying down arable land to permanent Grass, especially if hay is to be removed, it is essential to supply, not only nitrogenous, but an abundance of mineral manures, and especially of potash, a large quantity of which is removed in the crops, and must be returned. When the Grass is not mown, but fed, the exhaustion is much less, but it is greater when consumed for the production of milk than when for that of store or fattening increase.—(*Nature*.)

METEOROLOGICAL OBSERVATIONS.

CAMDEN SQUARE, LONDON.

Lat. 51° 32' 40" N.; Long. 0° 8' 0" W.; Altitude, 111 feet.

DATE.		9 A.M.					IN THE DAY.						Rain.

REMARKS.

12th.—Unbroken sunshine throughout the day; starlight night.
 13th.—Dull and damp all day.
 14th.—Slight fog early; dull morning; damp afternoon.
 15th.—Overcast and mild.
 16th.—Cloudy morning; fine afternoon, with some sunshine.
 17th.—Generally cloudy in the morning; bright afternoon; gale and rain at night.
 18th.—Bright sunshine during day; cloudy evening; gale and rain at night.
 Another mild week, and generally fine; sun on the 12th quite warm.—G. J. SYMONS.

HORTICULTURE.

UNDER that familiar term, which in common parlance signifies the art of cultivating gardens, a great variety of subjects present themselves for consideration, each of which possesses interest to certain sections of the community. Those sections in the aggregate form a great army, engaged, as we believe, in an important and beneficent campaign in the furtherance of objects as worthy as any which can claim the attention of man. Making the world more productive of that which is good, making our surroundings brighter, ministering to the necessities of the poor, and adding to the wholesome requirements of the rich, is a pursuit than which no other has higher claims to encouragement. It seems desirable from time to time to see how we stand as a body; or, more correctly, to see how our work is moving, for stand still it cannot, as there must be either advancement or retrogression.

Looking back over the past few years it is impossible to ignore the fact that obstacles of varying magnitude barred the path of progress. This was not so in horticulture only, but even more seriously in the sister art of agriculture, also in most branches of commerce. The declension was general, and correlatively so must be the revival. All the branches of industry, all the means of producing wealth and promoting prosperity, can be reduced to two concrete forms—commerce and cultivation. These act and react on each other and influence everything. Art, science, professions, organisations of benevolence, and even missionary effort feel the strain when the wheels of commerce drag slowly and wearily along, or, what is worse, glide backwards. This movement is measurable and has been distinctly on the down grade in the past, but is clearly now on the ascent to prosperity. Trade returns tell us this unmistakably, and corresponding signs of improvement in the agricultural world are apparent. Land is letting better and the prospects of cultivators are brighter. Difficulties are often blessings in disguise in arousing to higher effort and stimulating to better things.

Activity appears noticeable everywhere, and in many respects progress is unmistakeable. Benevolent objects in the horticultural world are well maintained, conferences and associations are more numerous, better attended and better supported; thus knowledge is being gained and distributed that must exert an influence in developing the resources of the soil for the common benefit of all. There is a stirring individually for excellence, and a general bestirring in corporate bodies. The Royal Horticultural Society is advancing and increasingly gaining public confidence. It is working on lines we believe to be sound, and in this way gaining adherents. Special societies for encouraging the culture of different kinds of plants and enlisting recruits to the great floral army are heartily engaged, and accomplishing what could not possibly be done so well in any other way. Honours are being accorded on a broader basis than before, and many will observe with pleasure that special medals are being granted by the Veitch Memorial Trustees to good, assiduous, and successful workers for "services in horticulture." Mr. A. F. Barron is followed by Mr. Bruce Findlay and Mr. David Thomson as fitting recipients. In this way not only is merit rewarded, but encouragement is afforded to others who will doubtless be in due time enrolled in the list of worthies. All this savours of progress, and it is a pleasure to record it; but in

one respect perhaps advancement is fully too rapid—the manufacture of gardeners.

One of the greatest movements of the time is in the direction of fruit culture, and there appears somewhat of a rivalry amongst individuals and organisations in its "promotion." Newspapers are being half filled with letters on fruit, practical men, faddists, and, truth compels us to add, charlatans, joining in the discussion; these latter, however, not often finding expression in well conducted journals; and some writings in a medium of high position a correspondent treats lightsofely in another column. We cannot say we agree with all he says, but accord him space for utterance because he appears to write good-humouredly, and has had long experience in fruit cultivation.

One of the ancient city guilds is giving the weight of its influence in fostering the work, and no one who attended the annual dinner of the Master and Wardens of the Fruiterers' Company on Monday night last could have failed to recognise the earnestness and indeed animation that prevailed throughout the proceedings. The newly elected Master of the Company, Sir James Whitehead, Bart., ex-Lord Mayor, made an earnest and eloquent appeal on behalf of the object of his desire—British fruit grown in British soil for supplying the wants of the community. He asked for the help of all—the Board of Agriculture as represented by Major Craigie in procuring grants for teaching the elements and principles of horticulture and agriculture in village schools as an important and necessary form of technical education; he appealed to the Royal Agricultural Society through Col. Sir Nigel Kingscote, Bart., for co-operation, and to the richer City Companies for pecuniary help towards raising a fund for distribution in a manner which would do the greatest good to the greatest number, and thus improve the condition of landlords, tenants, and labourers by the extended and better cultivation of hardy fruits. The responses of the gentlemen named were encouraging, and even the Lord Mayor (Sir Henry Isaacs), who made a somewhat pessimistic speech, was so far converted to the views of the majority as to assist by a contribution. The zeal that is being displayed is admirable, the enthusiasm "catching," and both are requisite for the conduct of a campaign; but they must be tempered with wisdom, and the procedure guided by experience for achieving the best results.

Individual fancies must be made subservient to sound principles, and much that is fanciful is heard nowadays on the subject of fruit culture. Optimists appear at the moment in the ascendant, but there is a powerful body of pessimists to put on the drag; and practicalists whose minds are well balanced by experience—men who know the contingencies to which fruit culture is liable, and also the methods by which it can be best conducted to a successful issue—are, after all that can be said, the safest guides to follow in the important work. It is by a combination of influence, wealth, and workers that the most good can be done in this and other useful, desirable, and enjoyable branches of horticulture, and in all branches we are glad to believe that the spirit of progress is moving horticulturists onward to a time of greater prosperity.

OUR FRUIT SUPPLY—PEARS UNDER GLASS.

GARDENERS who can take a retrospect over the last half-century will, I think, not be able to fix upon any given time when the horticultural press was so freighted with matter bearing on the cultivation of our hardy fruits, especially Apples and Pears, as it has been for the last two or three years. The dry bones of old and effete orchards have had such a shaking of late as one has not any recollection of. The interchange of ideas and discussions that have taken place between men so situated as to have had opportunities of making themselves experts in the matter have been very interesting to onlookers, and no doubt profitable to many who are able to act upon the suggestions and instructions

advanced. Recent Apple and Pear Conferences have doubtless done something towards quickening those concerned into a more systematic and sustained effort to meet to a greater extent the ever-growing demands for these fruits from British orchards and gardens. It has, however, been the conviction of many who took part in these Conferences that they were projected and carried out on not very good lines, inasmuch as that collections made up of every scrag of an Apple or Pear that would exist in a locality were invited, instead of selections of the best comparatively few sorts that crop the most certain, and are worth storing or marketing when produced. The Conferences and the Blue Books concerning them were alike bewildering and embarrassing. A much more simple and effective method of instructing by such gatherings would have been to have invited growers to come forward with two, or at most three dozen of the sorts that were best all round for their districts, instead of a nondescript collection of mostly worthless varieties, for it is the opinion of those best able to judge that if the home demand is to be more fully met from our own orchards it must be done, not with collections, but with very limited selections, as at Chiswick last year. We want growers more than pomologists, growers who will concentrate their energy and skill on the peculiarities of the sorts which are best worth growing. It would be well if, in this respect, we took a leaf out of brother Jonathan's book. He does not load our Atlantic liners and crowd our quays with all imaginable sorts, but with enormous quantities of a few varieties skilfully sorted and packed.

All that has lately been said and done to swell our home Apple and Pear supply will doubtless do much good. Nevertheless it will not be of much practical use to many who are so situated as regards soil, and especially climate, that to attempt to grow Apples, and especially Pears, with success is simply impossible. The great mass of consumers in such districts must always look to distant producers for their supply. It is a wonder that amidst all the "plans" for improving Ireland and Irishmen little or nothing is said of fruit culture. I have a very vivid picture in my mind's eye of the most splendid crops of Apples in the north of Ireland I ever saw.

The hopeless and long continued struggle of many of us, against adverse circumstances, to produce, in many gardens especially, Pears fit to be eaten—even when they can be had in any shape—speaks much more for the patience and perseverance of both owners of gardens and gardeners than for their wisdom. In common with many others, no doubt, I have practised in districts where it was comparatively easy to secure crops of these fruit in highly presentable samples, and found that in other districts such success was simply impossible. In the latter wall trees have been nailed, and pruned, and lifted, and root-pruned, &c., while their produce, over a series of years, would not disburse the nail and shred bill. No doubt it is natural, and to some extent laudable, to attempt the supply of our own tables out of our own gardens, but in very many places Apples, and especially Pears, cannot be produced fit for a good dessert when they do condescend to smile on our efforts.

Good luscious Pears in autumn and winter are always a welcome feature of the dessert, and well they deserve to be. Now that glass houses can be erected at such comparatively little cost, there is no reason why the very best Pears should not be grown even in Britain's worst climates; and in many cases it would be better to clothe walls devoted to them with Currants even, and put up a house for Pears. The wonder is that this has not been more frequently done. Peach houses go up in great numbers, and who will say a single word against the Peach? This, however, can be said as between it and the Pear. The Peach cannot be stored and husbanded till the time that other fruits are scarce as Pears can, and the cultivation of the Peach involves twice the labour, if not more, than Pears require.

The quantity of splendid Pears that can be taken annually from an orchard house, say 50 or 60 feet long, 24 feet wide, and of proportionate height, with a small amount of labour, would astonish many who are not conversant with the results of such an arrangement. It is imagined and said by some that orchard-house Pears are deficient in flavour because less exposed to the air. This may be, and doubtless is, the case in wrongly constructed houses; but where the ridge and sides of a house can be extensively opened for ventilation the very reverse is the case, for the quality of the fruit is superior, and no finer looking nor finer flavoured Pears can be produced by any other means. In a properly constructed orchard house there is as much of a circulation of fresh air, often more, than in the open.

Let well drained not over-deep borders of, for the staple, good sound loam be put into such houses, and the sides and roof clothed with single cordons on the Quince stock 2 feet apart, the body of the house stocked with pyramids or open bushes on the same stock, and all other things being equal I do not know how a more splendid or serviceable return can be had from a glass house. The

single cordon is to be recommended, because in a limited space varieties sufficient to give a supply over a long season can be planted, and when one has to be substituted for another it can be done without causing large gaps. Both cordons and bushes can now be supplied by nurserymen in a bearing condition at reasonable prices, and so well do the Quince roots bear removing that in most instances fruit is produced the first season, so that long waiting is not necessary. The trees should be planted sufficiently deep to cover the union of the Pears with the Quinces. I do not recommend rich borders to begin with. Some bones should be mixed with the turfy loam when the border is first made. When Pears on the Quince are in full bearing it is scarcely possible to over-feed them, and in a well-drained border they take large supplies of water. My experience of these trees leads me to say all I can against summer pinching, and I never touch the trees in the way of pruning or pinching till I am well satisfied they will not break into growth again. The autumn pruning when in leaf and fruit is nearly all the pruning required.

Pears are not nearly so troubled with insects as Peaches and Plums under glass. They are, in hot seasons, sometimes attacked with red spider, but the hose or engine soon clears them off. If the Pear scale should be found on any trees from the nursery petroleum and water soon make short work of that enemy. When a Pear happens to make its appearance outdoors in this region of rain, cloud, and late spring and early autumn frosts, the difference between it and its fellow under glass is scarcely describable. This refers as much to flavour as to appearance. Pears under glass come with a clear shining speckless rind. The trees crop regularly too if the imprudence of heavy crops is avoided. This is, however, a sore temptation when none can be had outdoors, and a large family demand has to be met.—D. THOMSON.

EMIGRATION OF GARDENERS.

(Continued from page 60.)

BEFORE our friend proceeded to follow his own business—i.e., that of gardener, inquiries were made as to the prospects of the leading horticulturists in New York and Boston, with the result that accompanied similar applications in this country—viz., "Glad to be of service, but too many applicants; more hands than we know what to do with;" but one leading firm in New York on receipt of his testimonials (English) requested to be called upon, or would write when anything suitable offered. Becoming impatient a start was made on All Fool's Day for Boston, the Maine farmer seeing our friend off with "tearful eyes," taking, as it proved, "a last fond look," for when our gardener wanted a friend the farmer had joined the majority.

Boston (Massachusetts) was drawn blank, and the leading firm in New York had no prospects, consequently work had to be sought elsewhere, and was secured in Long Island, thirty miles from New York, on an Asparagus farm—i.e., the farmer had thirty-two acres of Asparagus, where a stay was made of two months, or during the Asparagus season, at 22 dols. per month and board. The Asparagus heads were tied up in bundles about 5½ inches in diameter at the bottom, 4 inches at the top, and 6½ inches in length. Five hundred bundles were sent off daily on the average the whole season, realising from the salesman in New York 17 cents per bundle. Nine men were employed in cutting, &c., the crop being considered a paying one. The soil was very sandy, New York manure was largely used, the blanching system of culture was practised, the soil being ploughed over the rows, which were 4 feet apart, and after cutting, the soil was ploughed off. Cutting Asparagus commenced on May 6th, and ceased July 4th.

Passing into Pennsylvania our friend gained employment in haymaking, Wheat and Oat harvesting at 2½ dols. per day with board. Moving south, Delaware offered nothing better than hoeing Sweet Corn and gathering Tomatoes for canning at 1½ dol. per day, finding his own board, the labour being for the most part supplied by coloured men. Maryland was entered in the time of cutting Yellow Corn. When it is dry it is pulled off in cobs, husked, and carted to the barn. The corn stalks are carted when matured, and used as fodder for cows. Work of that kind was paid for at 75 cents per day with board, or 15 dols. without board, the labour being coloured; in fact, the farm to which these remarks apply is owned by a coloured farmer, both himself and wife being at one time slaves on the same estate. This was in the neighbourhood of Texas, twelve miles from Baltimore. It was now October, and as winter must be passed a move was made to Baltimore. Gardening being at a discount, an engagement was entered into for three months oyster dredging at 17 dols. per month and board. This was found a very rough and hazardous mode of getting a living, but being midwinter an engagement was entered into with another master for another three months, or until the end of March. This work was remark-

able only for the uncertainties of harvest and of life, and the recoups were sought by poaching the "reserves."

On April 1st, 1887, our adventurer set out for Philadelphia, and obtained work with a florist at once at 20 cents per hour the first month, and for the remainder of the season (to October inclusive) at 35 dols. per month with board. The "western craze" at that time rose to fever heat with those that had saved a few dollars, and our friend fell a prey to the epidemic; but as winter was no time for explorations, the setting out was deferred until spring, and as dollars will not keep any more than crowns in England without wearing the pockets out, a trip was decided on to the "falls"—Niagara of course—and the "lakes." Work of that kind soon ended the dollars, which made no difference only in the exchange of spending to earning, as work came in the shape of chopping wood—i.e., felling Pine timber or lumber—eleven miles from Toronto, Canada, at 19 dols. per month and board, there being nineteen men, "I being the worst man and the worst paid, through only being capable of trimming," the "choppers" getting 32 dols. per month and board. This lasted eleven weeks, snow a yard deep, messing in a log house. Ice cutting on the lake Ontario afforded employment for a fortnight at 1½ dol. per day without board. Ice 2 feet thick, clear as crystal, was stored in ice-houses double boarded—i.e., with a space between the boarding, the ice put in in blocks, all cracks or interstices filled with sawdust, covering with a good thickness of sawdust, and over all with straw.

Gardening prospects being very uninviting in any part of the Canadian Dominion a move was made to Buffalo, then on to Cleveland, Ohio, without prospect of work of any kind; hence a start was made to Chicago, meeting with the "cold shoulder," as the German gardeners were preferred. Experience, however, always tells, thus a job was obtained on a grain-laden steamer bound from Chicago to Milwaukee as deck hand—i.e., load and unload at 8 do's. per return trip. Spring had now returned, therefore he set out for St. Louis, Missouri, getting work in a vineyard, disbudding and tying Vine shoots at 1½ dol. per day without board, refusing a strongly urged permanent engagement, as the "western craze" had not been cooled by the cold of the Canadas, or if it had the fever broke out strong again, so a journey was made from St. Louis to Kansas. No work there for gardeners; in fact, the German element again predominated; therefore the course was pursued—due west into the wilds, with nothing but cattle ranches, very few settlements, and homesteads twenty to thirty miles or more apart. There the "almighty dollar" lost its potential attributes. Cowboys are described as "gentlemen at home," and yet will take "your last dollar for a revel;" even the Indians in the Reserve were "careful to entertain strangers." Enough!—gardeners have no business west, and the "fever" having abated a start was made to Memphis, Tennessee, where work was had at cutting Wheat-heads only, the straw being not more than a foot high; the pay, 2 dols. a day with board. From this point (Memphis) worked up the river (Mississippi) as far as Dakota, harvesting all the way, getting 2½ dols. per day with board. The work being finished in Dakota, and having some cash (though but paper) a trip was resolved on—not north, as the rigours of the Canadian winter yet obtained in the recollection. South; therefore made New Orleans, Louisiana, by river—a long trip, the incidents of which need not burden our theme.—UTILITARIAN.

(To be continued.)

FLOWER CULTURE FOR PROFIT.

TEA ROSES PLANTED OUT.

ALTHOUGH Tea Roses succeed well in pots when on their own roots, they are more profitable when planted out under glass, this whether trained thinly over the roof or grown as large bushes. In the latter case a span-roofed house may well be given up to them, the Roses being either put out in raised borders or on a level with the single pathway through the centre. In addition to the bushes grown in the body of the house a few might also be trained thinly up the roof, or say one at every principal rafter, or at 4 feet distances, about three leading growths being laid in each instance without unduly shading the other occupants of the house. If blooms are wanted as much as possible throughout the winter these may be obtained without very hard forcing and without detriment to any plants of *Maréchal Niel* there may be trained up the roof, and as this is undoubtedly the most popular of all Roses it is advisable to give the greater portion of the rafters up to it. Neither a very deep nor an excessively rich border is needed by Roses, and we find a depth of 30 inches, including about 6 inches of rough drainage, ample. Nothing suits them so well as a compost consisting of three parts of light turfy loam roughly chopped up to one of good leaf soil, a moderate amount of grit, a liberal

sprinkling of charred garden rubbish greatly improving the mixture. If there is no fibre in the loam then ought a rather smaller proportion of this be used and a part of old Mushroom bed refuse added. In this the Roses ought to be planted firmly, and if disposed about 3 feet apart each way will occupy all the space without becoming unduly thick.

In many instances only the roofs of greenhouses can be given up to Roses, and in this case if they are thinly trained, *Azaleas*, *Camellias*, *Clivias*, *Ferns* and a few other plants will thrive very well underneath. Not unfrequently narrow borders, raised or otherwise, might be formed underneath the staging along the front of the house, but if it is more convenient the Roses will succeed nearly or quite as well planted outside and brought through the front walls or just below the sills. Ours outside are 2 feet wide, the same in depth, being raised about 1 foot above the level and enclosed by a 4½-inch brick wall with a cemented top course. We have roof-trained Roses both on their own roots and worked on healthy *Briar* stems, and in this case the latter answer equally as well as own-root plants. We find *Maréchal Niel* just as liable to canker and fail on their own roots as on the *Briar*, but would not plant any worked on the *Manetti* stock if they were given to us, these being most liable to canker, but to this I must again briefly refer. In addition to *Maréchal Niel* there are a few other varieties of Tea or Noisette Roses admirably adapted for root culture, notably *Safrano*, *Lamarque*, *Homer*, *Reine Marie Henriette*, *W. A. Richardson* and *Cheshunt Hybrid*, the two first named being my favourites. Each ought to be capable of covering a roof area 12 feet by 10 feet, the *Maréchal Niel* covering double that space in a comparatively short period. Moderately strong wires 10 inches apart taken across the roof through eyes screwed into the rafters, and not less than 9 inches from the glass, another 3 inches not being too much for *Safrano*, is all the trellising needed for the spreading plants, while for rafter Roses about three wires, 6 inches apart, may be very simply strained up the roof.

Much pruning and training are not required by Tea Roses, though they ought not to have matters too much their own way, or they may quickly wear out. At the outset they should be staked uprightly, and only lightly shortened back, and being in good health may be permitted to develop a few blooms, but will be profitable or not according to the quality and quantity of strong suckers that push up from the base. These will branch and flower grandly, thus stopping themselves, and subsequent pruning consists merely of cutting all blooms as they form, the shortening back of straggling branches and removal of all spray in October. There being good room some of the stronger branches ought to be staked out, the slight depression given to these causing them to push up stray shoots certain to produce extra fine blooms. Occasionally an apparently worn out plant will be renovated by being freely cut back, and partially thinning out the main branches every autumn will serve to keep others in robust growth. The roof plants, with the exception of *Maréchal Niel*, and in a lesser degree *Lamarque*, may be treated very similarly to the bushes, the roof being gradually covered with the best of the shoots formed, these inevitably flowering abundantly as they advance. In time the roof becomes covered with branches, and each autumn, or after a comparative resting period, these should be freely thinned out and shortened back to about half their length, the more weakly spray being cut cleanly out. *Lamarque* is of very vigorous habit, forming long shoots during the summer, and which at pruning time should be only lightly shortened, grand blooms being pushed out from nearly every joint on all well-matured growths. *Maréchal Niel* will be referred to in my next communication, and the prices that have been obtained for Roses stated.—M. H.

PLANT FOOD.

ONE of the signs of the times, speaking horticulturally, is the extent to which chemical manures are now employed in gardens. I suppose there are few gardens in which they are not in use to the benefit of crops. Now, though it has not been my practice to purchase made manures for many years, still I have often had opportunities of testing these, and it is only fair to say that, though many of them are expensive, still taking into account the small quantities required in gardens, and the good results which invariably follow their use, they cannot be said to be dear. One of the largest manure manufacturers told me the other day that their experience with gardeners, among whom they are trying to establish a general manure, was that they had an objection to cheapness. I do not know about that, but there is such a thing as being penny wise and pound foolish, and if a gardener thinks he can procure a better manure by paying a few shillings more each year there is nothing blameworthy in that.

Then, again, it is only fair to say that gardeners have had little help from men of science, who have devoted their researches almost exclusively to agricultural subjects, with the result that farmers with any intelligence worthy the name are in a position to purchase those manures best suited to their land and crops at a very reasonable price. We occasionally meet with an unbeliever in the efficacy of chemical manures. These are said to be either scourges which take every particle of good out of the soil, or they are held to burn the crops, and in either case are to be given a wide berth. No doubt it is possible that both these things may happen; but, as has been often said, the bad shillings do not prove that every shilling is bad, and therefore to be shunned. I think also that it is a great mistake to look upon these manures as stimulants, and of value merely to give an extra push at a critical period to the already hard-worked plant. They may be useful in such cases, but such a view does not give a fair representation of their value. A good chemical manure is essentially a food, and as such is to be made use of in the same way as we apply water—that is, in order to meet a felt want. In a certain sense farmyard manures are stimulants, for if employed indiscreetly it is found that they produce a rushing growth followed by collapse, the principal reason for this being the absence of those elements of plant food which are or should be present in every carefully prepared chemical manure.

There is perhaps nothing more difficult to estimate than the quantities of such food required by plants. For one thing soils differ so much, some holding in sufficient quantity one or other of the foods which chemistry is in general obliged to supply. Or if applied to a soil its retentiveness may be of so poor a nature that a heavy rain may practically destroy the best part of a good dressing, while the same rain in the case of soil of a retentive character would simply diffuse the manure through the upper strata, and make it more available for plant roots. Generally, therefore, each cultivator must find out for himself what is best to do with his own particular land. In fruit borders and flower borders under glass the case is much simplified, and as regards pot culture we have the matter practically in our own hands.

In order to make the remarks which follow plainer it may be indicated that plant nutrition is largely in the hand of Nature, the bountiful mother having supplied to a wonderful degree the wants of her inanimate children; but chemists long ago found that a few elements were presented in too slight proportions to meet the wants of plants when cultivated. None of these entered very largely into the composition of plants, but slight as their position is they could not be dispensed with, and the plant kept in health and vigour at the same time. By means of water culture—that is, growing certain plants in water with the addition of some chemical elements—German chemists many years ago demonstrated the necessity of the presence of in order that plants might perfectly fulfil all the functions of their nature. About the same time a French chemist was showing that soils—that is, cultivated soils—contained sufficient food for plants with the exception of a few elements. Thus, Professor Wolff to 1000 parts of water had 938.028, and of solid matters 61.972, or to 94 per cent. of water added 6 per cent. of solid matter. In 1000 parts these solids were thus proportioned:—

Phosphoric acid	8.234
Lime	10.370
Potash	9.123
Magnesia	1.403
Sulphuric acid	2.254
Chloride...	0.885
Nitric acid	29.703
And one drop of ferric chloride.						

Other chemists proved that a plant performed all its functions properly with a ratio of solids to water of one to over 3000. Ville, the French chemist, whose researches have practically revolutionised agricultural chemistry, showed that nitrogen, potash, phosphoric acid, and lime were the only foods necessary to add to the least fertile soils. Instead of water Ville employed calcined sand, and by the addition of soda, magnesia, sulphuric acid, chlorine, ferric oxide, silica, manganese, nitrogen, phosphoric acid, potash, and lime proved that with the addition of water and the carbonic acid derived from the air plants performed all their functions perfectly. But Ville was a practical chemist, and on a farm where he made experiments he found that the soil had in sufficient quantities for the food of plants the seven minerals which supply the soda to plants, but that nitrogen and the other three must generally be introduced by the cultivator. Curiously enough, however, any one of these foods may be within reach of plants, but impossibility to assimilate the particular food renders its presence of no use—thus the atmosphere is diluted with nitrogen, an element which enters largely into the albuminoids of plants, yet only a certain group of plants are capable of securing a sufficiency from the air. Very much the

same remark applies to the mineral agents which may be present in soils, but in a form which the plant cannot reduce to a useable condition. It will be seen how the base on which plant feeding rests has been simplified. In another paper I hope to have something to say on the more practical matter of feeding plants.—B.

HYBRID DENDROBIUMS.

THE hybrid Orchids raised and sent out within the past ten or twelve years have taken prominent positions amongst the most beautiful plants in cultivation, and the genus *Dendrobium* has contributed liberally to the list of favourites. At least twenty distinct hybrids have flowered and been described, some have been illustrated, and a few have been certificated. They all possess some special characters of their own, but one remarkable fact must strike an observer who has given some attention to these hybrids, and that is the regular manner in which the floral form and habit of the parents are combined in the seedlings. This occurs even where the crosses have been reversed, and the experimental hybridiser may fairly expect when he succeeds in effecting a cross that the characters of the pollen and seed plants will be nearly equalled combined in the offspring, whichever species is made the seed-bearing parent. The leading practical results of hybridising *Dendrobiums* have been to increase the diversity of colouring, to impart or add to the fragrance, and to prolong the duration of the flowers, with, in several cases, greater vigour of habit.

A brief review of the principal hybrids that have yet flowered will illustrate what has been accomplished amongst the *Dendrobiums*, and for convenience they may be taken in alphabetical order. First, then, is *D. Ainsworthi* from *D. aureum* crossed with *D. nobile*, which originated in Dr. Ainsworth's garden at Lower Broughton, near Manchester; it first flowered in 1874, and was certificated by the Royal Horticultural Society February 18th of the same year. This is one of the best known and most beautiful hybrids yet obtained amongst the *Dendrobiums* either in the ordinary form, which has white sepals and petals and rich crimson lip, or in the more deeply coloured variety *roseum*, admirably portrayed in the first volume of Mr. B. S. Williams' "*Orchid Album*" (t. 20). The lip shows the influence of the two parents, for while the form closely resembles that of *D. aureum*, the colouring is that of *D. nobile*. The flowers are large, freely produced, the plant is of strong habit, and the feathering of the crimson blotch on the lip imparts a distinct appearance to the flower, which is readily recognised. *D. Leechianum* and *D. splendidissimum* come very near in characteristics to *D. Ainsworthi*, and are from the same parents.

Several hybrid *Dendrobiums* are but little known, and amongst them we must count *D. chlorostele*, raised at Burford Lodge, between *D. Linawianum* (*moniliforme*) and *D. Wardianum*. It has white sepals, petals white at the base, purple at the tip, the lip rich purple in the centre, and with a zone of pale yellow, the column green. *D. chrysodiscus*, and its variety *oculatum*, are also Burford Lodge hybrids from *D. Ainsworthi* and *D. Findlayanum*, the former being the pollen parent. It is distinct, but the seed parent's characters predominate, the lip resembling that closely in shape, but differing in colour. The greater portion is white, with a dense bronzy red and yellowish blotch at the base. The sepals and petals are bluish tinted, giving the white flower a very delicate appearance. The original hybrid was certificated by the R.H.S. in February, 1888. The variety *oculatum* has rather more colour in the flowers, and a reverse cross has been named *melanodiscus*. *D. Cybele* (*Findlayanum* and *nobile*), one of the Veitchian hybrids, is noteworthy for the fact that the pollen parent (*nobile*) has here had the greatest influence, the peculiarity of the *Findlayanum* growth being slightly retained, also a little of the lip colouring. *D. Dominianum* (*nobile* and *Linawianum*) is interesting historically as presumably the first hybrid *Dendrobium* known, having been raised by Mr. Dominy in Messrs. Veitch & Son's Exeter Nursery. The flowers are purple, tinted deeper in the lip, and altogether distinctly of the *nobile* group.

A valuable addition was made when *D. endocharis* was raised in

the Veitchian nursery at Chelsea. In this case *Dendrobium japonicum* was the seed plant and *D. aureum* supplied the pollen, the result being a peculiar intermixing of characters and a most useful hybrid. The flowers are nearly white, the lip having a basal purple blotch, and they possess a delicious fragrance resembling Violets. In habit the plant is more like *D. aureum*, strong growing and most floriferous. A *Dendrobium* with such characters was not likely to be disregarded by such a close observer as Mr. Seden, and he soon utilised it as a seed parent, a cross with *D. nobile* producing the beautiful *D. euosmum* and the variety *leucopterum*. In the original form the sepals and petals are white, tipped with pale purple, the lip having a deep purple central blotch. The exquisite fragrance of *D. endocharis* is here combined with the floral attractions of *D. nobile*, the result being all that could be desired in a *Dendrobium*. In the variety *leucopterum*, shown by Baron Schröder and certificated by the Royal Horticultural Society April 9th, 1889, the flowers are of medium size, very delicate and beautiful, the sepals and petals narrow and white, the lip long, crimson in the centre, the apical half pure white. It is of slender growth, but free flowering. Another variety named *roseum* has also been noted.

Coming now to a more recent production we have in *Dendrobium Juno* (fig. 13), shown at the last meeting of the R.H.S. Orchid Committee (Jan. 14th, 1890), by Sir Trevor Lawrence, an exceedingly handsome hybrid well meriting the certificate awarded. It was raised from a cross between *D. Wardianum* and *D. Linawianum* (*moniliforme*), and again we have to remark the strange fusion of characters that occur in so many hybrid Orchids. The flowers are of excellent shape, the sepals and petals broad, but especially the latter, white, deeply tinged with rich crimson from the apex towards the base. The lip is nearly circular, having a maroon central blotch bounded by a yellowish tinge, then a white zone and a purplish marginal band. In form and colouring this will rank with the best of the artificially raised *Dendrobiums*.

Dendrobium Leechianum, of which a flower is represented in fig. 14, resembles *D. Ainsworthi*, but is much larger, the sepals and petals being tinged with bright purplish crimson, like some fine varieties of *D. nobile*. The lip is large, open, and marked with very rich crimson in the throat, the tip being also tinged with a similar colour but somewhat lighter. The petals are broad with a wavy margin, and the whole flower has an appearance of great substance. A great additional recommendation is the sweet fragrance it possesses, like *D. aureum*. The plant flowers very profusely, and lasts for a considerable time in beauty.

Some time ago Mr. Swan wrote me as follows concerning the origin and qualities of the hybrid:—"I flowered several of the

FIG. 13.—DENDROBIUM JUNO.

plants in 1881 during January and February, and then considered them sufficiently distinct to deserve a name. I find it a free grower and an abundant bloomer, and one of its chief recommendations will be that it may be hastened into flower by Christmas, and by keeping it quiet and cool it may be retarded till March and April, or probably even later. The parents were *D. nobile* and *D. aureum*. *D. nobile* was fertilised in January, 1875, with pollen

taken from a strong plant of *D. aureum*; in fact this was one of the strongest pieces I have seen, with growths 2 feet long covered with bloom. The flower of *D. nobile* soon withered but did not fall, the seed pod quickly formed, and the seed was ripe, and sown in June of the same year on the top of a basket containing *Dendrobium crassinode*. The seedlings were first observed in February, 1876. Being so small I did not disturb them for some time. However, when they had pseudo-bulbs about three-quarters of an inch long I pricked them out into two pots and hung them up in

FIG. 14.—DENDROBIUM LEECHIANUM.

the East India house. They continued to grow well, so that by the spring of 1880 I placed many of them in baskets 2 inches square."

Another of the Burford Lodge hybrids is *Dendrobium Luna*, shown and certificated on Jan. 14th last. It is a hybrid between *D. Ainsworthi* and *D. Findlayanum*, the pseudo-bulbs and growth resembling the latter parent. The flowers are about 2½ inches across the lip, nearly circular, but somewhat oval, creamy white, yellow at the base, with a few purple veins in the centre. The sepals and petals are creamy white, faintly tipped with purple, the petals slightly broader than the sepals. The flowers are borne on short racemes of three or four each, and it appears to be both free-growing and free-flowering.

The other hybrids in this genus must be dealt with very briefly. *D. micans* (*Wardianum* and *litiflorum*) has rather attractive white and purple tinted flowers, and a shiny wax-like surface. *D. porphyrogastrum* (*Huttoni* and *Dalhousieanum*) is an interesting hybrid, in the flowers of which mauve and purple colouring predominates, with somewhat of the pollen parent's floral form. *D. rhodostema* (*Huttoni* and *sanguinolentum*) partakes largely of the pollen parent's characters. *D. Schneiderianum* (*Findlayanum* and *aureum*), raised at Fallowfield, possesses the habit of the seed parent and the principal floral characters of the pollen plant, except that a purple tint is introduced. *D. splendidissimum* (*aureum* and *nobile*) is the reverse cross from that which resulted in *D. Leechianum*; it is very similar, but the variety *grandiflorum* is much superior in size, and is indeed one of the finest of the section yet obtained. *D. Vannerianum* (*japonicum* and *Falconeri*) has delicately pretty flowers, white tinted and tipped with purple. Other crosses have been raised, but have either not flowered or have proved too much like one of the parents to be distinguished under special names. In some cases this is probably due to the crosses not being satisfactorily effected, in others perhaps to accidental defects of condition or organism in one of the plants.—LEWIS CASTLE.

STORED ROOTS.—These will play an important part in the supplies during the next three months, and they should be preserved as well as possible. Where they have been stored in large heaps some may be decaying, and these should be thrown out, all indications of growth re-

moved, and then store anew. Onions that are beginning to sprout should be discarded, and the soundest of the bulbs placed on one side for late use.—M.

NOTES ON FORCING VEGETABLES.

CAULIFLOWERS.—The Cauliflower is one of the best of vegetables, and very highly esteemed, especially if it can be had early. It is true that there are some good late Broccolis so late that there need be but a short interval between them and the early Cauliflowers out of doors. But in some districts in the north, and especially in this part of Lancashire, Broccolis are sometimes destroyed by severe frosts and continued wet weather. I may say the sorts that I have found stand the weather best here are Sutton's Late Queen, Leamington, and Knight's Protecting. This winter up to the present Veitch's Model and Gilbert's Late Queen are standing well.

But to return to the Cauliflower. It is by no means difficult to have fine heads fit for use quite a month or six weeks earlier than they can be had out of doors, provided a pit heated by hot-water pipes or a sufficiently deep frame can be spared for them. The seed should be sown in the end of August or early in September, and when strong enough should be lifted and wintered in a cold frame.

In the beginning of February or earlier the pit or frame should be prepared by placing a thick layer of manure over the bottom, then place over this about a foot depth of fibry loam, or the best soil that can be had. If manure cannot be had some approved artificial manure should be well forked into the soil before planting, and a little sprinkled round the plants and watered in on two or three occasions during their growth will prove very beneficial.

When the pit is ready to receive the plants lift them carefully with a trowel from the frame in which they have been wintered, and plant them in rows 2 feet apart, and 18 inches or 2 feet from plant to plant, then water with a pot without the rose, and if the work has been properly done they will have received little or no check, and will grow away. Begin with a temperature of 50°, gradually rising to 60° with plenty of ventilation on all favourable occasions. As they advance in growth they should never be allowed to suffer through insufficient watering. As the heads are forming liquid manure should be given about three times a week. In about three months after planting nice white heads may be looked for. Early London and Dwarf Erfurt are good sorts for early work.

PEAS.—Few attempt to force this vegetable to any extent. They are, however, sometimes grown on the border of a Peach house to a limited extent, and found to produce their fruit tolerably well. Anyone attempting to force them in this way should give them all the ventilation possible without injuring the Peaches in order to have them sturdy.

We do not advocate growing Peas in this manner unless they are specially wanted, but they may be with advantage brought on under glass for planting out as soon as the weather is deemed suitable. For this purpose some use turf, some pots, and others boxes, and Peas may be forwarded very successfully under all the different modes.

I prefer narrow boxes 8 or 10 feet long with holes in the bottom. They are only temporarily nailed—that is, the nails are not driven close in, but sufficient is left to be taken hold of by a pincers, so that when they are taken to the drills where they are intended to be grown, the boxes laid on their side by the drills, the nails can easily be pulled out, the bottom off they are placed in the drill and the sides lifted over the tops. In this way the soil is not broken, and the plants receive no check. There are plenty of early varieties, the thing is to find out what sort does best in the soil and district. I have found Veitch's Selected Extra Early do well here, followed by William I. Peas forwarded in this way should not be brought on in too strong a heat, or they will be drawn up weakly. The thing to aim at is short sturdy growth. They should be well exposed before being planted out.—G. HILTON.

ALLOTMENTS.

I know very little of the terms of the recent Allotments Act, but if as I have been informed that under the stipulations it affords reasonable facilities for respectable and industrious working men to acquire a piece of land for their own use at a reasonable rent, it rests entirely with them to prove that it is of real benefit. First of all, a man ought not to aspire to a larger holding than he can conveniently attend to, as one man's spare time for such work is no guide to that of another, and a small plot well cropped and otherwise well attended to is much more creditable to its occupier than a larger one where slovenliness is conspicuous; besides, the

quality of the produce is of treble value. And, again, it is very unjust to the hard-working man, whose plot may be in the best of order, to see his neighbour's plot overrun with weeds, the seeds of which are blown in all directions. A periodical inspection by those in authority would do good, warning such as neglect them that they run the risk of having to quit their holdings.

Allotment holdings are not new in the country, because many landed proprietors have for years set off a convenient portion of their land for the purpose; and one of the best that I know in the south of England is on the Chilston Park estate, the property of Mr. Akers Douglas. There is a field of about twenty acres, irregular in shape. It has, however, been squared off with cart roads running in two or three directions for the convenience of occupiers, and the land laid out in half an acre, quarter, and one-eighth acre portions, with paths of convenient width running between each. I have known this as an allotment field for over thirty years, although I am told it has been known as such for more than twenty years beyond that time, but the system of inspection above described has always existed and worked satisfactorily. The rent charged is at the rate of 32s. an acre free of all taxes. The 11th of October is the time for changing or reletting. The soil is principally a light sandy loam overlying a thick bed of red sand, consequently it is much improved by the addition of road sidings and plenty of manure, yet the soil is not difficult to work.

For one to notice, as I have done, the difference between the ideas and methods of cultivation and cropping twenty or more years ago, and at the present time, it is remarkable to see the improvements that have taken place. At the former time and for years after little besides Potatoes and Turnips were grown until the soil became "Potato sick," and crops were very poor, but now all things are changed for the better. The ground is well manured, as during recent frosty and moonlight nights I saw several men and boys wheeling out the manure there. During the day others were digging the manure in, but it may be as well to enlighten my readers upon the subject of how the manure is obtained. First of all is by careful collecting of manure from the highways, which is mixed with road sidings, mud from ditches, ashes, and other refuse, together with a good portion of pig manure (as most of them keep a pig), and a quantity of lime added, which is frequently turned before using. A few join together and purchase a quantity of London dung, which they get down by rail to within half a mile of the field at the rate of 4s. per ton, while some purchase a few bags of "wool waste" of 5 cwt. each. This has been found a most lasting manure, and is used more for fruit trees, but is too expensive for general purposes.

Now about cropping. This is done in a more practical way than formerly, for while most of them grow a variety of vegetables as well as Potatoes for their own use, others grow Mangold Wurtzel, Swede Turnips, and cattle Carrots, and then market their produce, yet several have planted their holdings with Gooseberries, Black and Red Currants, all of which they sell.

One man, Collins by name, planted his half acre with Strawberries and Raspberries, a quarter of an acre of each, and according to the returns he showed me for last year they must have paid him handsomely. His account was a little over a ton weight of Raspberries and just under a ton and a half of Strawberries, all sent to the London market. On two mornings I see he sent as many as fifty-two pecks at a time of Strawberries, and several of forty, thirty, and less. The sorts are Sir Joseph Paxton, President, and Trollope's Victoria, while of Raspberries he grows only Carter's Prolific, a sort much sought after in this locality. The whole plantation is three years old, and looks promising for the coming season. When asking the man about the preparation of his land he said he only dug it deeply, but added plenty of manure, and since that has attended to surface hoeing and mulching, never digging amongst them. He also added that with the planting and subsequent use he had applied sixteen tons and a half of London dung alone. Although it was an exceptionally good year for small fruits, especially Strawberries, yet I must give the man credit for his venture, and wish him success in the future. The land being light the great enemy to ward off is red spider, which quickly attacks them, where, as is the case, there is no water to be obtained, hence the reason for mulching so heavily.—THOMAS RECORD.

EARLY CAULIFLOWERS.

SEED of Suttons' First Crop sown the first week in February and the plants grown sturdily will produce white compact heads the size of a pint basin by the first week in June. For two years I sowed to succeed plants raised in the autumn, but the autumn sowing followed those sown in February, consequently I have discontinued sowing in the autumn. I use a box 12 inches by 16 inches and 3 inches deep filled with soil; sow the seed thinly, and place in gentle heat. As soon as the seedlings appear the box is removed to a shelf in a greenhouse close to

the glass to prevent the plants drawing, care being taken in watering. As soon as the plants are large enough I place the strongest in small 60-pots; the rest are pricked off in boxes; they are then placed in a close frame for a few days, and gradually hardened until fit for planting out. Those in pots will well pay for the little extra labour, as they receive no check when planted out. Should the weather prove unfavourable after planting I turn an inverted pot over the plants at night, also on cold days to protect them from wind and frost.—T. N.

EVENTS OF THE WEEK.—To-day (Thursday) the Royal Society meets at 4.30 P.M. The Essex Field Club's annual meeting will take place in the Public Hall, Loughton, on Saturday, February 1st, at 7 P.M., and the Society of Arts will hold a meeting on Wednesday, February 3rd, at 8 P.M. Messrs. Protheroe & Morris announce an important sale of Orchids at their Cheapside Rooms on January 31st, in which *Vanda Sanderiana* will form a leading feature. Sales of *Lilium auratum* and other bulbs also take place at the same rooms every Wednesday.

— AT a meeting of the Trustees of the VEITCH MEMORIAL FUND held on the 23rd inst.—present Dr. Robert Hogg (in the chair), and Messrs. T. B. Haywood, G. F. Wilson, and H. J. Veitch—it was decided to give four prizes, consisting of four bronze medals and £5 each, at the Chrysanthemum Centenary, which opens on November 11th; and also a special silver medal each to Mr. Bruce Findlay of Manchester and Mr. David Thomson of Drumlanrig, in recognition of their valuable services to British horticulture.

— THE WEATHER IN THE SOUTH.—During the past week in the metropolitan district, and the south of England generally, the weather has been mild for January, with frequent and rather heavy rains. Strong winds have prevailed, and much damage has resulted in exposed positions and along the coast. In the West of England the damage has been greatest; much land is under water, and in the Vale of Gloucester it is reported that hundreds of sheep have been drowned by the Severn hursting its banks.

— THE WEATHER IN THE NORTH.—The temperature has been lower during the past week. On the night of the 22nd $5\frac{1}{2}^{\circ}$ of frost was registered. Very high winds and heavy rains have been frequent, the night of the 25th being especially stormy. Snow fell on the evening of the 23rd, and sleety showers over and again; these, with the melting of the snow on the hills, and the great rainfall, have brought down the streams heavily, and caused much flooding of the lower grounds. In my last note 40° at 9 P.M. on the 16th should have been 50° ; 40° has been quite common.—B. D.

— THE WORSHIPFUL COMPANY OF FRUITERERS.—The Master and Wardens of the Fruiterers' Company for each year are chosen on January 25th, the feast day of the Conversion of St. Paul, the patron saint of London. At a court held this year Sir James Whitehead, Bart., ex-Lord Mayor, was, in consequence of his exertions in promoting fruit culture, elected to all the privileges, including the position of Master of the Company for the ensuing year. In this capacity he presided at the annual dinner which was held at the Albion Hotel, Aldersgate Street, on Monday evening last, and was supported by the Lord Mayor, Sir Henry Isaacs; the City Sheriffs, Colonel Sir Nigel Kingscote, Major Craigie, H. R. Williams, Esq.; and civic dignitaries. About 100 persons sat down. Horticulturists were represented by Messrs. A. F. Barron, T. F. Rivers (Mr. Shirley Hibberd being unable to attend), and J. Wright, who, it may be safely said, did not give their adherence to all that was heard on fruit culture, though they did not appear to enjoy the proceedings the less on that account. A copy of Mr. Wright's essay, bound in morocco, and containing a beautifully illuminated frontispiece, which included a view of the Old Mansion House, the Arms of the Fruiterers' Company, and those of Sir James Whitehead, was presented to the Master by Mr. H. R. Williams. Sir James accepted it in graceful terms and publicly thanked the author for his useful work.

— APPLICATION OF PHOTOGRAPHY TO METEOROLOGY.—The Council of the Royal Meteorological Society have arranged to hold at 25, Great George Street, Westminster, on March 18th to 21st next,

an exhibition of instruments and photographs illustrating the application of photography to meteorology. I am therefore instructed by the Exhibition Committee to invite your co-operation, as they are anxious to obtain as large a collection as possible of such instruments. The Committee will also be glad to show any new meteorological instruments or apparatus invented or first constructed since last March, as well as photographs and drawings possessing meteorological interest.—W. MARRIOTT.

— GARDENING APPOINTMENT.—Mr. J. Leicester, late foreman at Hillsborough Castle Gardens, has been appointed gardener to Lord Farnham, Farnham House, Co. Cavan.

— WE are informed that the seventh annual Show of the HULL AND EAST RIDING CHRYSANTHEMUM SOCIETY has been fixed for Wednesday and Thursday, November 19th and 20th.

— APRICOTS.—May I be allowed to ask the readers of the Journal who are successful in APRICOT CULTURE the best method to adopt which may tend to secure a crop in the Midlands?—C. R.

— VINCA MINOR VARIEGATA.—Can any of your readers inform me if there are two varieties under this heading, the one having white and the other blue flowers? The latter is now in bloom out of doors. I fancy we should have two sorts as stated, both variegated.—CORK.

— MAY not the old couplet as to SNOWDROPS quoted by Mr. Arnott in your paper of the 23rd inst. have been written when the old style prevailed, and have been quite applicable? Candlemas Day would, as regards the season of the year, have then fallen about what is now January 22nd.—FRANCIS STERN.

— THE TEDDINGTON CHRYSANTHEMUM SOCIETY's annual Exhibition is announced to be held on November 13th and 14th, 1890, Mr. David Anderson, the Nursery, Teddington, being the Secretary. It is probable that the summer Shows of the Twickenham and Teddington Societies will be united this year, but the autumn Shows will remain distinct as before.

— IRISH APPLE, GIBBON'S RUSSET.—So much has been written lately on the merits or demerits of numerous well known Apples that I venture a word in praise of this little-known sort. Hitherto it has been localised in the south of Ireland, and quite possible neither scions nor trees have as yet reached England. I may be wrong. Can any of your readers give me the information?—B. H. C.

— PRESTON AND FULWOOD HORTICULTURAL SOCIETY.—The twenty-eighth monthly meeting of this Society (the sixth of the present season) will be held in the large room of the Castle Hotel, Market Place, Preston, on Saturday, February 1st, when Mr. William Bardney of Norris Green, near Liverpool, will read a paper, "Notes on Fruit Culture, Extension *versus* Restriction." Chair to be taken at 7.30, prompt, by the President.

— CAT EATING MELONS AND CUCUMBERS.—We have known dogs to eat Peaches and Strawberries, but a correspondent says his cat likes Cucumbers and Melons. "H. S. E." writes:—"I am fond of Melon growing, and enjoy a real good fruit. My children are the same, and we can always eat one right away. Even one of my cats is sure to eat one if he can get near enough; he has destroyed a fruit uncut before now. The brute also eats Cucumbers as they are growing."

— DOUBLE HYACINTH LA TOUR D'AUVERGNE.—For flowering at Christmas this old variety is invaluable. I saw during Christmas week several boxes of this excellent Hyacinth with spikes averaging 6 inches in length. They were planted close together in boxes very soon after the arrival of the bulbs from Holland, in ordinary Hyacinth soil, and were plunged out of doors in cocoa fibre refuse until fit to remove under glass, then placed in a cool house for a fortnight before, placing them in heat.—S. H.

— PEAR HUYSHÉ'S VICTORIA.—We do not often see this mentioned, which to me is somewhat unaccountable. We have a good-sized well-formed pyramid of it on the Pear stock, and during the past nine seasons it has never once failed to bear a crop. Some seasons we have gathered two bushels of fruit from this single tree. We did so in 1888, and in 1889 we had fully three pecks of it stored for use during December. With us the fruits are somewhat small this season, but it is sound, and promises to be of good quality. Huyshé's Victoria is by no means a showy Pear, but it is very serviceable, and deserves a place or trial in most gardens.—I.

— **ROSEMARY RUSSET APPLE.**—We have received from Mr. Turner of Slough very fine samples of this excellent dessert Apple, which he considers not only as one of the best in quality at this season of the year, but one of the most profitable to grow. In a plantation which includes many varieties in a bearing state this is regarded as the most productive, the trees being every year almost overlaid with fruits. Those sent are above medium size, $3\frac{1}{2}$ inches wide at the base and 3 inches high, narrowing acutely to the apex. They are more or less covered with russet veins, and flushed with red on the side next the sun. The flavour is sprightly and excellent, and the variety would seem to have claims to more extended cultivation.

— **BLANCHING ENDIVE IN HEAT.**—I have found it a good plan to take up and pot a few plants of Endive at intervals for meeting the demand, removing all decayed leaves, also the soil from the collars of the plants, which prevent any more decaying, giving water freely to prevent flagging. After allowing the water to drain off I tie a sheet of brown or white paper round the pot and plant, tying paper round the top for obstructing light. In this way the Broad-leaved Batavian can be blanched in about four or five days by placing the plants in a temperature of 60° to 65° . The curled or moss varieties will not endure so much heat. I have had plants of Endive perfect models of ivory white, fully compensating for the little trouble in producing them.—G. W. W.

— **THE ESSEX FIELD CLUB.**—The tenth annual general meeting will be held Saturday, February 1st, 1890, at 7 P.M., in the Public Hall, Loughton, Essex. The report of the Council for the year 1889 and the Treasurer's statement of accounts will be read and submitted to the meeting. The election of new members of the Council and Officers for 1890 will also take place. The annual presidential address will be delivered as follows:—The Migration of Birds, by E. A. Fitch, F.L.S., F.E.S. An ordinary meeting (the 11th) will also be held for the proposal and election of new members. Exhibitions of objects of natural history, geology, or microscopy, are solicited for the above meeting. Intending exhibitors are requested to communicate with the Hon. Secretaries, Messrs. William Cole and G. B. Cole.

— **THE GREAT INTERNATIONAL HORTICULTURAL EXHIBITION** at Berlin will be held from the 25th of April till the 5th of May, and we hear that the preparations have advanced in a most satisfactory manner. The Emperor, on the suggestion of the President of the Exhibition, Dr. Lucius von Ballhausen, has appointed the large gold State medal for the most meritorious horticultural production at the Exhibition, and eighty other medals will be granted. All the German Governmental railways, as well as several private companies, have promised to return unsold objects free. The Farmers' Club of Berlin have also established a prize of 100 marks (£5). Every means will be employed to arrange the Exhibition in the most effective manner. Programmes may be obtained from the office of the General Secretary, Invalidenstrasse 42, Berlin, N. Germany. Entries close on the 1st of March.

— **A FEW MORE WORDS FROM AMERICA.**—Thanks for your insertion of a few words respecting the doings of our old horticultural friend, Mr. Laurence in his American home. In a further letter just received, in which he encloses *Primula* blooms, he says:—"You will see (a copy of the *American Florist* is referred to) that *Roses* and *Carnations* head the list for cut flowers, and the quantities grown are to a Britisher enormous, and the way *Roses* are mailed (*i.e.*, posted) is something also to wonder at. My friend Reid of Chambersburg has house after house, each containing 18,000 to 20,000 in $2\frac{1}{2}$ -inch pots, struck in summer, and retailing at 1 dol. per dozen; very few H.P.'s. Winter has not yet come, and Christmas Day was like a fine Easter Sunday in England, and the grass is still green. It is stated by old sailors that the Gulf Stream is several hundred miles nearer the Atlantic coast. If really so, that may account for the phenomenal weather we have had the past two years, but we do not like it. It is too English-like for us."—W. D.

— **THE LATE MR. JOHN HENDERSON.**—In your last issue you gave a notice of the death of this eminent horticulturist, as remarked in the *American Florist*. Mr. John Henderson was a son of the late Mr. E. G. Henderson, of the Wellington Road Nurseries, and was, previous to his going to America, a partner with his brother, Mr. Arthur Henderson, and his uncle, Mr. John A. Henderson, in the Pine Apple Place Nurseries, the firm being that of J. A. Henderson & Co. At that time the Pine Apple Nurseries, Maida Vale, had a world-wide reputation, and one of your earliest contributors on the establishment of the Journal, the late Mr. Thomas Appleby, was for years the Orchid grower, and an

esteemed colleague of mine. I well remember the dissolution of partnership by the retirement of Mr. John Henderson, as it fell to my lot to assist materially in making up the partnership accounts. The late Mr. John A. Henderson was a warm supporter of the Gardeners' Royal Benevolent Institution from its formation to the time of his death. Mr. Andrew Henderson, another brother of Mr. John, and Mr. Arthur Henderson, were in partnership with their father, Mr. E. G. Henderson, at the Wellington Road Nurseries for years, and he is now connected with the old Pine Apple Place Nurseries, and I believe his brother, Mr. Arthur Henderson, is still living.—W. D.

— **SPRAYING FRUIT TREES WITH ARSENITES.**—At the meeting of the American Association for the Advancement of Science, held at Toronto, this subject was taken up by Professor A. J. Cook. He said: Again, as our wild fruits are more cleared away we only need to spray our Apples once to destroy the codling moth, and can treat the Plum trees three or four times with Paris green or carbolated lime in case we have only occasional showers. For the Apples we can use London purple, 1 lb. to 200 gallons of water. For the Plums against the curculio we must use Paris green, 1 lb. to 200 or 300 gallons of water. Respecting the injury done the foliage by the use of arsenites, he said: London purple is more injurious to the foliage than is Paris green, and white arsenic—arsenious acid—is more harmful than is either London purple or Paris green. This is doubtless owing to the soluble arsenic which is quite abundant in London purple, and almost absent in Paris green. London purple may be used on Apple, Plum, Cherry, Pear, and most ornamental trees, but on these should never be stronger than 1 lb. to 200 gallons of water. If the application is to be repeated, as it must be for the curculio, to prove effective, or if it is to be used in June or July, Paris green should be used in the same proportion as above, or else we should only use 1 lb. of London purple to 300 gallons of water. I now think that this necessity is more due to time of application than to the fact of increased quantity of the poison. If the arsenites are to be used on the Peach to defend against the curculio Paris green only should be used, and that not stronger than 1 lb. to 300 gallons of water. The injury done to the foliage is never immediately apparent. It usually shows somewhat the second day, but the full injury is frequently not manifest till the fifth day, and often not till the tenth. He likewise demonstrated that there is no danger of cattle being poisoned by eating the grass under the sprayed trees. Professor Clarence M. Weed of Columbus, O., read a paper on a similar subject—remedies for the Plum curculio. An experiment with Cherries was made, spraying half an orchard with London purple, 1 lbs. to 160 gallons of water. He then picked Cherries from sprayed trees and unsprayed trees, and in every case there were more wormy Cherries on the unsprayed than on the sprayed trees. The average was—unsprayed trees, eight per cent. of wormy Cherries; sprayed trees, three per cent. of wormy Cherries. The benefit from the spraying hence was 75 to 10 per cent. Experiments were also made with Plums when an orchard of Plums was sprayed with London purple several times. An enormous crop was the consequence, although two untreated trees had their entire yield destroyed. He concluded that very much of the damage done by the curculio could be safely and cheaply prevented by the use of arsenites. Professor Saunders of Ottawa expressed his opinion that Paris green was a better arsenite to use than London purple.

DESTROYING THE EUCHARIS MITE.

I HAVE observed of late that several of your correspondents have claimed credit for good cultivation of the *Eucharis*. I have no wish to speak lightly of the merits of any successful cultivator, especially if he or she be an amateur or a beginner; but given conditions which are at all favourable I should hardly consider the *Eucharis* the most difficult plant in the world to grow. Indeed, when we remember how it is baked in one place, stewed in another, and poisoned in a third, according to the whims of the different cultivators, and that it not only survives, but does fairly well in each case, one would be inclined to consider it a remarkably easy plant to cultivate. In practice many others beside myself have found it so. But having succeeded ourselves shall we call our brother gardeners unskilful who have failed to do the same? Because we have never been troubled with insects at the roots of our plants shall we say there is no such thing as *Eucharis* mite? I might just as well say there is no such thing as influenza because I do not happen to have that disease myself.

I have grown *Eucharises* under favourable conditions and succeeded. I have attempted to grow them under other conditions and have miser-

ably failed. The favourable conditions need not be related, so I will confine my remarks mostly to the other side of the question.

Some plants were bought at a public sale three or four years ago. They did not look in particularly robust health, but I have seen many look worse, and they quickly responded to a little liberal treatment. They were shaken out, divided, potted, and they started growing fairly well. After a while the leaves became flabby and some of them decayed. On looking at the roots some of these were found to be decayed too. In a short time they started well again, but the same unhealthy symptoms came on before the growth was completed, and this state of things went on for two years. The plants were attended to in watering, &c., and received much the same treatment as was given to other plants which succeeded admirably in former years, but which had now passed out of my hands.

Last spring it was decided to kill or cure them. On turning out the bulbs and washing them they were found to be very much infested with small white insects and what looked like eggs. The bulbs were decayed in places, and the insects and eggs were in them to a considerable depth. They were then subjected to the following process: Two or three layers were peeled off each bulb, and any holes remaining were then pared round with a pointed knife.

A mixture was then made as follows:—Half a pint of Fir tree oil and a quarter of a pint of petroleum were shaken together in a bottle and then mixed with a gallon of rather hot soft water.

The manner of mixing is a little important, because if it is properly done the ingredients remain mixed, and may be used for other purposes besides our present subject. Measure out a gallon of the hot water, and after thoroughly shaking the Fir tree oil and petroleum together in the bottle do not allow sufficient time for them to separate again, but pour a little of the water into a third vessel, and then, with the bottle in the left hand and the vessel containing the water in the right, pour them both into the third vessel together, when the water will become milky and sufficiently thick to prevent the petroleum again separating.

The bulbs were placed in this mixture for twenty minutes and then in a tub of clear water for a similar length of time. They were then potted, placing three bulbs, or at least what remained of them, into a 6-inch pot. I have the pleasure to say that they not only lived, but commenced growing almost immediately, and are now nice healthy plants, nearly 2 feet through and filling 10-inch pots.

Now I think I have said something to prove first that there is an insect which attacks the roots of the Eucharis; secondly, that it is useless attempting to grow the plant without first getting rid of the enemy; thirdly, that it may be got rid of with comparatively little trouble, though I do not think a careless or slovenly person will ever get rid of it. Of course there are several details which will suggest themselves to the thoughtful reader, but perhaps I had better mention some of them for the benefit of those who are not thoughtful. I took my plants into the open air on to a vegetable quarter to shake them out, the old pots were washed and left outside, the place where the plants had been standing was watered with petroleum, and the plants when newly potted were placed at the other end of the house.

I have been induced to write a line on this subject because I happen to know that some excellent gardeners have been blamed for failing to grow the Eucharis well, and the idea of the Eucharis mite being the cause has been ridiculed, because some writers had said there was no Eucharis mite, or if there was it was only the result of bad cultivation.—WM. TAYLOR.

FORCING RHUBARB AND SEAKALE IN LEAF HEAPS.

As there has been some correspondence lately on the above subject, I will state the system practised here in the hope that it may be of service to others who are in a position to secure a good heap of leaves. This season I cut Rhubarb on New Year's Day, and Seakale the day after Christmas, from roots placed in at the end of November. In 1888 Rhubarb was put in on November 23rd, and the first dish cut on December 24th. I do not know whether that would be considered quick or not, but it is as early as it is wanted here. As the leaves are gathered in the autumn they are wheeled into a sheltered corner outside the garden and made into a square heap in which boxes are sunk. The top of the box is about a foot below the surface, and the boxes about 3½ feet deep without bottoms. Boxes 2½ feet deep will do for Seakale. About 6 inches of ordinary garden soil is used, and the crowns are packed in as closely as possible. Seakale roots have 3 inches of space between them. No water is needed if the soil is at all moist. Boards are placed on the boxes and covered with a few inches depth of leaves. A small hole is left, and the boxes examined every other day, and the hole made larger or smaller for regulating the heat. I find this is always strong in the early part of the winter. Once I remember by neglecting to leave any opening, and not opening the boxes for a week, the roots

were found to be in pulp. With that exception I have never had any difficulty in having Rhubarb or Seakale as early as wanted.—A. THOBURN.

NEW ROSES.

NOTWITHSTANDING the immense number of new Roses which have been sent out during the last twenty years, there is little sign of abatement in the number that our French friends are so kind as to send us. Perhaps they think as the President of the Chamber of Deputies appeared to do, although I rather think he must have put his tongue in his cheek when he said it—I mean when he alluded to the generous hospitality France had shown to the strangers who visited Paris at the time of the Exhibition, appearing to think that by making the charges at hotels, restaurants, &c., double what they usually are, they are conferring a favour, so it would almost seem as if the French Rose growers thought that the more Roses they could foist upon a credulous public the more kindness they show us; and although I fancy that those who are willing to have the *experimentum in vili corpore* made on them must be very sensibly diminished, for burnt children dread the fire, still it must to a certain extent be a want which this flood is designed to meet, and no doubt there is to a certain extent that remnant of curiosity and eagerness for novelty which are the cause that produces the effect. When we look at our Hybrid Perpetuals and Teas and see such *loves* as Marie Baumann, A. K. Williams, Charles Lefevre, &c., it may be well asked, Can there be anything we want? Yes, we want a white one of the form and substance of the latter named flower, and a yellow Marie Baumann or A. K. Williams, not such a thing as Gloire Lyonnaise. I can hardly yet forgive Guillot for palming this off on us as a yellow Hybrid Perpetual. He has done such good work in giving us the splendid Teas which have come from his establishment, that it was a pity he should damage the trust we had in him by sending us this; if he had sent it as a Hybrid Tea and not called it yellow, we should not have found fault with him. Not yet has it proved to be beginning of a new race any more than La France, from which so much was expected; but oftentimes the hopes of hybridisers are frustrated.

TEAS.

In taking these first, I do so because this class is unquestionably highest in favour at the present time. Nor is this to be wondered at: their lovely colour, their delightful fragrance, and lasting qualities clearly give them a claim on all lovers of flowers. There are two names which are especially conspicuous in this class—Guillot and Nabonnand, and it is a proof to old fellows like myself how time goes on. I recollect when we used to call the present head of the firm “young Guillot,” and now the young one has become “old Guillot,” and there is a young one to take his place. One has written slightly of Nabonnand, and as a raiser of Teas for exhibition he has not done much for us, but he has gained our favour by that exquisite buttonhole which he gave us last year in L’Idéale, and we may have some prospect. Of the twenty varieties four are sent out by

NABONNAND ET FILS.

Adeline Outrey.—Very vigorous and free flowering; flowers medium size, full, clear yellow, tinted with rose, centre chamois.

Madame Marguerite de Saras.—This is apparently one of the Dijon race, and the description of its colouring might very well be used for old “Gloire.” It is said, however, to be of perfect shape, which certainly that Rose is not, but we have had so many of this race with high sounding pretensions, that we may well hesitate at any fresh claimant.

Marguerite de Thezillat.—This would seem to be one of the red Teas, for the colour is said to be that of the red H.P.’s, and the form imbricated, while the centre is said to be yellow.

Madame Marie Usher.—This is another of the Dijon family, but different in colour, which is said to be carmine.

BERNAIX.

Georges Farber.—Flowers very large, supported by a long firm foot-stalk; colour velvety purple, veined with dark red; centre cochineal red, passing into cerise carmine, colouring very variable.

Madame Marthe du Bourg.—Flowers large, full, outside petals large and of great substance; colour white, washed with violet carmine red, passing into chrome yellow washed with garnet red.

Madame Phillipe Kuentz.—Flowers erect, large, full; colour rose cerise, passing into salmon flesh colour.

Madeline d’Aoust.—It is very difficult to imagine what this Rose is like, unless it be something of an enlarged W. A. Richardson. Form elegant, two-coloured, rosy flesh in the upper portion of the petals, centre nankin, reminding us of the tints of Souvenir de la Malmaison and W. Allen Richardson.

GUILLOT ET FILS.

J. B. Varonne.—Flowers, large, well formed; colour ranging from china rose to bright carmine, with coppery yellow centre.

Souvenir de François Gaulain.—Vigorous. Flowers large and well formed; colour varying from magenta red shaded with violet to dark violet shaded with carmine.

SCIPION COCHET.

Maman Cochet.—One of the largest flowers in growth. Flowers with very short footstalk, outside petals very large, those in the centre in the form of a rosette; colour rosy flesh washed with carmine, shaded with nankin yellow. This magnificent variety, which is figured correctly in the "Journal des Roses," will not be sent out until the autumn of 1890, and is dedicated by M. Cochet to his venerable and very worthy *mère*, aged eighty-five years. I think that this advertisement oversteps even the most effusive of our home productions in that line.

SOUPERT ET NOTTING.

Duchesse Marie Salviati.—Flowers large, full, well formed; colour orange chrome yellow, shaded with tender carmine rose, centre rosy peach.

Gustave Nadand.—Flowers cupped shape; colour clear vermillion, shaded with carmine lake.

TÉSNIER.

Gloire des Cinorés.—Flowers very large, full, cup shaped; colour coppery yellow, reflex of petals wine red, with gold yellow centre, constituting new shade of colour.

Madame Adolphe de Tarlé.—Flowers large, with large petals, cup shape; colour pure satiny white, with canary coloured centre.

BONNAIRE.

Jeanne Guillaumex.—Flowers large and well formed; colour blush red, largely shaded with salmon, centre metallic red on straw yellow ground.

Souvenir d'Auguste Legros.—Large and well formed; colour fiery red mixed with shaded crimson; buds very long, and of large size.

MOREAU-ROBERT.

Madame Moreau.—Flowers large and well shaped, colour clear coppery yellow, shaded at the centre with deeper tint; reverse of petals rose and apricot yellow.

LEVEQUE ET FILS.

Madame Olga.—Very vigorous. Flowers large and well formed, holding themselves erect; colour white, very delicately and finely shaded with yellow in the centre.

KETTEN FRÈRES.

Miss Marston.—A Rose raised by Pries, but sent sent out by this firm. Apparently not a very strong grower *Assez vigoureux*, pure white, bordered with deep rose, centre yellow lighted with peach.

CHARRETON.

Marquise de Folton.—Vigorous. Flowers cupped shaped; colour saffron yellow, centre carmine rose.

The list presents several noticeable features; thus several of those who have supplied us with new Teas are absent, while such names as Tesnier, Charreton, and Ketten are new to us, while of the better known growers we have comparatively few. Nabonnand is very modest in his list, on which, however, as far as pretty Roses go, we are inclined to look with more favour since he has given us *L'Idéale*. Another feature is the large number of red and high coloured Teas, there being nine out of the twenty-one of this character, and I think this is much to be deplored. Already, as I believe, we have too many of these, and the whole beauty of the class will be destroyed if we get a quantity of these glaring colours, which may well be left to the Hybrid Perpetuals. Another point is that there are a number of cupped flowers. I do not for a moment deny that there are some beautiful flowers of this shape amongst the Teas already, but they are not in my opinion equal in beauty to the long pointed bud of others. *Souvenir d'un Ami* is a lovely Rose, but I do not think that it can be compared with a good Anna Olivier or Comtesse de Nadaillac.

For these reasons, then, I do not look very hopefully to the new Tea Roses to add much to our enjoyment; of course, it may turn out otherwise. There may be a "dark horse" amongst them; but judging from our experience of the past, and the description given to us of those for the present year, I had rather not "give odds" on any of them.—D., Deal.

P.S.—I find, either by printer's error or slip of the pen, that in the "Rosarians' Year Book" I have credited Mr. F. Cant with the fine bloom of Miss Ethel Brownlow instead of Mr. Ben. Cant.—D., Deal.

DRESSING ROSES.

I MUST ask permission for the insertion of a few lines on one point only on Mr. Pemberton's letter. I think he quite misunderstands my contention as to his action as a member of Committee. When a matter has been discussed on the Committee of any Society, and that Committee has passed a resolution to be submitted to the general body of its members as their recommendation, no member of it, whether present at its decision or not, is, I believe, at liberty to speak or write against it. It is as if a matter were discussed by the Cabinet (to compare small things with great) and a measure had been agreed upon, and when it was brought forward some member were to rise in his place and oppose it.

That has occurred, as in the case of the Duke of Wellington and Huskisson, but the latter got very short shrift. Of course, if not a member of Committee he might do what he liked.—D., Deal.

CULTIVATION OF HARDY FRUITS.

THE cultivation of hardy fruits in this country is a subject of great importance to the landowner, cultivator, and consumer, and deserves the serious consideration it is receiving in the gardening and other papers at the present time. No one can deny the fact that the demand for good fruit is yearly increasing all over the country, and that enormous quantities of Apples are imported from America, Australia, and the Continent to supply our markets, which, I think, might be successfully and profitably grown at home if a better system of culture and selection of varieties were adopted. Some writers aver that our climate is too moist and too cloudy to grow really fine Apples, a statement which few will admit who have had anything to do with Apple culture in the south and western counties of England. As regards quality I have no hesitation in saying that our best home-grown Apples are superior to any of the imported varieties I have met with, and I have tasted a great many of the American and Australian grown Apples, which are dry and juiceless compared with the brisk rich aroma of our crisp succulent home-grown fruit.

As to climate there are favourable situations all over the country from north to south, where Apples may be profitably grown in good seasons by selecting the best soil and situations and procuring proper varieties to suit the climate. But, as a matter of fact, the Apples grown in the north cannot compete in quality with those grown in the south. It is different, however, with small fruits which can be grown as successfully in the north as in the south. Gooseberries grown in the north are superior in quality to those cultivated in the south, and Strawberries, Red, White, and Black Currants, and Raspberries are as good in the north as they are in the south. The climate and a great quantity of the land in South Wales is well adapted for growing fruit of the best quality but neither the soil nor the situation have been taken advantage of, and there are few orchards of any kind in Glamorgan or the neighbouring counties, and what are have been sadly neglected. The trees appear to have been planted indiscriminately and allowed to grow as they pleased and nothing more done to them ever afterwards, and the results are poor crops of miserable fruit not fit for market.

The treatment is different in gentlemen's gardens, where none but the best varieties are grown. Here the trees have been properly planted, manured, pruned, and trained in pyramidal form, and kept in a clean, healthy state by adopting a regular system of washing and syringing them with an insecticide in winter. The trees here, and elsewhere in this district, which are treated in this way, produce heavy crops of fine fruit in ordinary seasons, which compare favourably on the exhibition table with those grown in the best fruit districts in England. It is a wonder that market gardeners, and others, have not gone more into fruit culture in this district in the past, where it would be sure to succeed, and where there is always a ready market for it in the large towns, and teeming populations in the mining valleys. Pyramidal trained trees are the most suitable for market gardeners. They are easier managed in the way of pruning and gathering the fruit; besides, the fruit is not so liable to be blown off in storms as they are on high standard trees. If the trees were planted in rows 20 feet apart, and 12 feet in the row, with the best market sorts, and sure bearers, such as Apples Keswick Codlin, Lord Grosvenor, Lord Suffield, Ecklinville Seedling, New Hawthornden, Stirling Castle, Alfriston, Potts' Seedling, Lane's Prince Albert, Nelson's Glory, Wellington, Worcester Pearmain, Rymer, Beauty of Kent, Beauty of Hants, Annie Elizabeth, Waltham Abbey Seedling, Cox's Pomona, Cox's Orange Pippin, and few other really fine varieties might be planted which are shyer in fruiting than those named.

Of Pears—Jargonelle, Williams' Bon Chrétien, Louise Bonne of Jersey, Beurré d'Amanlis, Beurré Diel, Marie Louise, Pitmaston Duchess, Glou Morceau, Durondeau, and others. Plums—Victoria, Kirke's, Pond's Seedling, Transparent Gage, Bryanstone Gage, Prince Engelbert, Jefferson, and Orleans. The space between the trees could be planted with Gooseberries, Raspberries, Strawberries, Currants, and vegetables, until they have grown sufficient to occupy the whole space. If the trees are properly attended to in pruning, manuring, and kept clean and healthy, they will become fruitful in five or six years after planting, and by the time they are ten years old they will produce excellent crop of fine marketable fruit.

Pyramidal trained trees cannot be grown satisfactorily in orchards where horse and cattle are allowed to graze, as it would be impossible

to protect them thoroughly from these. But if trees were planted with a clean stem of say not more than 4 feet it would be a great improvement on the old system of planting them with a stem 6 and 7 feet high before branching. The shorter stems could be easily protected from sheep by barbed wire guards, and horse and cattle should never be allowed to enter the orchard. If this method was adopted, and the trees planted 21 feet apart, they could be kept lower, and more under

"Profitable Fruit Growing"—will have a wonderful effect in the production of fruit in future by teaching all interested how to grow and market it in the best condition possible. To say the least, I consider the essay a masterpiece of its kind—a real acquisition, which cannot fail to do an immense amount of good, and raise the status of fruit culture in this country to a pitch it has never attained before.—A. PETTIGREW, *Castle Gardens, Cardiff*.

FIG. 15.—REV. W. WILKS, M.A.

the control of the cultivator. Besides the great advantage it would be in gathering the fruit, which would not be so liable to be injured by high winds.

A particular friend, and, I might say, one of the best gardeners in the country, in writing to me some time ago on the cultivation of hardy fruits, said that a certain distinguished statesman in his speeches had done more to raise the status of hardy fruit culture in this country than all other things put together during the century. Well, taking that for granted, I venture to say that Mr. Wright's prize essay—

REV. W. WILKS, M.A.

WE have pleasure in having been able to secure a portrait of the above gentleman for engraving in the *Journal of Horticulture*. We desired to do this because Mr. Wilks has not only been an ardent horticulturist for many years, and has practised the ancient art of gardening in its most modern aspects at Shirley, but more particularly because of the position he occupies as Secretary of the Royal Horticultural Society. This is a very honourable office to fill, but is no sinecure to a gentleman

who is earnest in discharging the duties pertaining to it. Working assiduously and gratuitously in the interests of the Society, Mr. Wilks has won the confidence of the Fellows, and to his clear judgment and active endeavour a large share of its increasing prosperity is due. Elected on the Council and appointed Secretary at a critical time, he has proved himself a "man for an emergency." Broad minded, free from the suspicion of pedantry, a good listener, great worker, and forcible speaker, he has done yeoman service to the Society, which is growing in influence and usefulness under his guiding hand. Mr. Wilks wisely recognises the work of special societies, not regarding them as opponents of the Royal Horticultural Society, but helpers in the advancement of national horticulture, of which it is the accredited head, and no one is more warmly welcomed at the festival gatherings of those societies than he is. We can say on their behalf, and on behalf of the Fellows of the Royal Horticultural Society, in the words of a famous statesman as applied to one who honestly tried to do his duty to his country, "We are all proud of him."

CULTURE OF THE MUSCAT GRAPE.

So much has been written of late years on the cultivation of the Grape in general by so many successful cultivators, that at the present time it is difficult to bring forward anything new on the subject; but the principal object of my paper is to bring into notice a class of Grapes which of late years have very much gone out of cultivation, or (as the more popular saying is) out of fashion. Grapes, I suppose, are subject to changes; and these are not at all times made without some sacrifice, and old favourites are often brought forward again to begin life anew. In the rage for changes many good Grapes are well nigh forgotten, and probably by many have never been seen. The most popular varieties of the present day are brought to a high state of perfection, owing, no doubt, to improved facilities in the form of houses better adapted for their successful cultivation, and the improvements in obtaining artificial heat, also to advanced knowledge of the constituents of the soils and manures, which play an important part in their successful cultivation.

We have not had many recent additions to the list of Muscat-flavoured Grapes, and it is questionable if some of our later additions will bear comparison with our old favourites when flavour is the primary consideration. We have advanced slightly in size of berry, and doubtless some of the old varieties might be improved in that respect if brought under the high cultivation of the present day. Our old and almost neglected varieties, such as the Grizzly, Black and White Frontignans, Chasselas Musqué, and Muscat Hamburgh are of the finest flavour, and not surpassed by any save that still valued variety Muscat of Alexandria. The Frontignans appear to have passed out of date owing to the smallness of their berries, and I am afraid the Grizzly Frontignan would not find favour generally in the present day owing to its peculiar colour, but it can be grown to produce fair size berries. A friend once in walking through a vinery where this variety was grown remarked, "What a bad colour your Lady Downe's Grape is!" "Yes," I replied, "but the flavour is good," and after he had tasted it exclaimed, "I never tasted Lady Downe's Grape with such a flavour." "I suppose not," was my reply, "but that Grape is the Grizzly Frontignan." He was still more surprised to see it with such large berries, as he had mistaken it for Lady Downe's badly coloured. I believe the Frontignans might be very much improved in size of bunch and berry by high cultivation; they would then, I feel convinced, surpass some of our later introductions.

Chasselas Musqué is another variety which is rarely seen now, but which has a fine Muscat flavour, but is liable to crack its berries if not carefully cultivated. It can be had earlier than the Muscat of Alexandria, and is considered to be equally as good in flavour, and is valuable for early use where Muscat flavoured Grapes are required.

Muscat Hamburgh is also a fine Grape, and not cultivated to the extent that its fine qualities deserve. Some complaints have been made as to its having a delicate constitution, but I consider that is more imaginary than real, and when well grown it is good both in bunch and berry, and not to be surpassed by any black Grape for quality or appearance.

Among the more recent introductions Mrs. Pince and Madresfield Court Black Muscats claim a fair share of attention, although the former is not so often seen in the best condition as is the Madresfield Court; and it is only of late years that this variety appears to have come to the front, for I believe it was originally considered to be a late Grape,

but since it has become better understood its successful cultivation has been attained, and it makes a valuable addition to the list of black Grapes. Mrs. Pince's Black Muscat deserves to be well cultivated, for it is a fine flavoured Grape, and few would care to return to such varieties as Gros Colman after eating it. It forms a good companion to that justly esteemed variety Muscat of Alexandria, and I think it would be difficult to name a better black and white Grape for late use when quality is taken into consideration.—W. SIMPSON. (*Read at a meeting of the Liverpool Horticultural Association.*)

(To be continued.)

LUPINUS ARBOREUS.

OUR gardens are largely indebted to the Lupines for many ornamental flowers. Besides the annual species several of the perennials are also useful. The species under notice, *L. arboreus*, the Tree Lupine, will yield to none of these in decorative qualities. The specific name is, however, somewhat a misnomer, as, if left to its own devices, the plant will assume more the form of a decumbent shrub than of a tree. If properly staked and tied it will, however, make a fine object in the shrubbery border, or at the back of a border next a hedge or a wall. Grown as a wall plant it is very attractive, but should have a warm and sheltered position in every locality. I have grown the Tree Lupines for a few years, and am a great admirer of their beauty; but have been somewhat puzzled by the uncertainty of their duration of life. Thus, out of some seedlings raised about five years ago, four plants were kept, being all for which space could be afforded. Of these one died in its second year, one in its third, and another this year, the fourth still survives and is flourishing. Nor can the time of their death account for it. One died in late autumn, one in early spring, and the last in September. In the case of the last I am disposed to attribute the cause to its bearing a very heavy crop of seed, and to the plant being unable to recover from the exhaustion consequent on the process. I should be glad if any of the readers of the Journal could enlighten me on the subject, as it is when these Lupines are of a large size that they are most decorative and most useful from a garden point of view. In all probability the safe plan will be to consider them as biennials, sowing the seeds singly in pots, and planting out the seedlings without disturbing the roots, although I find they transplant fairly well when young.

L. arboreus was introduced about 1795, and is, I am led to believe, a native of North America, but my information as to this is not very precise. The original colours appear to have been lilac and yellow, but several intermediate shades may be obtained from a packet of mixed seeds. I have had pale creamy-white, pale lilac-white, pale, but bright, yellow, and the last plant whose loss I had to mourn was a bright lilac. This was grown in the back of a border next a high hedge, was carefully tied up, and when in flower attracted much attention, the handsome spikes of bright lilac flowers showing well on the fine pinnate foliage. If we may be pardoned a somewhat far-fetched simile it was like a Christmas tree laden with ornaments, but all of Nature's handiwork.

L. arboreus prefers a light but rich soil, but must have sunny sheltered position protected from the north. Should these requisites be afforded it, and a succession of seedlings kept to renew the stock, the grower will have no reason to regret making its acquaintance. We have very many beautiful plants among the hardy leguminosæ, and although I dare not say it is the most beautiful it will, at all events, hold its own among them. Time after time I have seated myself in a snug corner in his garden, a short distance from the Tree Lupines, and viewed them with admiration, an admiration perhaps not lessened by the knowledge that possibly by another season their glory would be departed, but that its memory would abide.—S. ARNOTT, N.B.

EDITORS AIRING THEMSELVES.

EDITORS of gardening journals, like other mortals, no doubt enjoy a change now and then, and if they cannot wholly leave their old habits behind them, they can at least wander into new fields, indulge in a literary romp, and have, what is good for all men in city pent, an airing. Wonderful men are editors, as a body. They "we" this and "we" that, or somebody "we's" for them, the authorship being shrouded in obscurity; but when those of a special class step beyond the confines of their own domain, and launch on the broad sea of general literature, to teach an ignorant world matters on which they assume to be wise, it is curious to notice they contrive to let the wide world know either who they are, what they are, or where they come from. This is presumably to give weight to their utterances, and as their object it must be assumed is the public good, not private distinction, they are permitted to have their airing. Let us hope they benefit by it, and benefit others by their words of wisdom scattered so freely around.

I have been led to allude to the interesting subject of editorial peregrinations by some copies of the *Times* which my master has been good enough to lend me, with the suggestion that I might, perhaps, write a little about them in the Journal, of which he is a reader, and to which he knows I send one or two communications a year. "Perhaps they will not insert what I send," I ventured to remark. "Oh yes they will," was the reply, "if you mind how

you put it." As that amounted to the expression of a wish, I felt bound to comply, and if I am lucky enough to "put it" in an acceptable manner, I shall certainly lose nothing, but may possibly gain a compliment, and that is something to a man who values his situation and has pleasure in trying to oblige those to whom he is under obligations.

The subject that has been exercising the minds of men—and editors—in the *Times* is fruit culture. A sort of triangular duel seems to have been going on, all the combatants appearing to be on very good terms with themselves, and—well, I will say "gentlemanly" towards each other. They may have dined together since, just as we are told barristers do who seem to fight each other so fiercely over cases in court. Be that as it may, they have had their little differences in public and—their airing.

I am not sure that I have been instructed in reading the letters in question, but I have been amused. There are six of them. There may be others I have not seen, but six suffice for me, two from each of three editors, for I take no account of a dozen others from persons who are not editors, therefore must be placed in the category of the commonplace multitude to which so many of us belong.

So far as I can make out, Editor No. 1 first stepped on the stage and said his little piece and retired. Next, Editor No. 2 came on and said his, which was different, of course, made his bow, and vanished. Then Editor No. 3 emerged from behind the scenes for a share in the public applause.

We have no theatre in our village, but from what I have read, actors appear as types of character. There is usually, I think, a "swell" in the company, generally a "funny man," and often a "heavy man." Judging entirely from the performance, if I were asked to indicate the characters, I should be inclined to regard No. 1 as the Swell, No. 2 as the Funny Man, and No. 3 as the Heavy Man of this piece in six acts.

Act 1. No. 1 enters. This gentleman says another gentleman "blames people for not buying an Apple of very poor quality," and goes on to say the public are not such fools as they are supposed to be, and they rightly refuse to grow English grown Gravensteins, and adduces as a model Apple the American Newtown Pippin, which cannot be grown here. He condemns King of the Pippins, and concludes by recommending the "Ribstone," and especially the Blenheim, for planting freely for market purposes. (Exit). No. 2 enters and says No. 1 puts his case "obliquely;" a claim then follows for Gravenstein and Newtown Pippin for amateurs, but though he thinks the American is often the better of the two, forthwith dismisses both as "curiosities." He praises King of the Pippins, and adduces supporting testimony, having also a good word for Cox's Orange Pippin, Stirling Castle, Golden Noble, Fearn's Pippin, Boston Russet, Lane's Prince Albert, and Dumelow's Seedling; but the pet of No. 1, the Blenheim, he says has been much overrated as a fruit for profit, and only after long waiting in a "place that suits it," it may prove a "pearl of great price." (Exit).

Enter No. 3. He says the true German Gravenstein ripens in this country, and the fruits are delicious, but many that are sold as Gravensteins are not Gravensteins; that the variety known as King of the Pippins, and generally grown under that name, is one of the most certain and profitable of table Apples, but is not the true King. The Blenheim he pronounces handsome, but too slow for people who want quick returns, therefore it was excluded from a list in a certain book, and he agrees generally with the sorts favourably mentioned by the previous performer. (Exit).

Act 2. Re-enter No. 1. No. 2, he says, "misleads in various ways," then gives an example of his research in analysing somebody's book for showing that King of the Pippins is not of fine flavour, and "Rue's" testimony to that effect was too old; that if the "Ribstone" did canker he was trying to cure it by grafting on dwarfing stocks; that a child who eats Apples would reject some of No. 2's, and that the Blenheim is worth any ten of them. (Exit).

Re-enter No. 2. He says he prefers the public judgment to individual tastes and fancies, yet would rather trust No. 1's taste in selecting fruit than framing arguments; that the Apple known as King of the Pippins sells better than any other of its season, and pays the grower; that it is quite sufficient for him that No. 1 admits the defects of the Ribston and Blenheim, the first by canker, the second by slow bearing, and "for a man of moderate means to plant the latter on another man's land would be to pledge himself to ruin." Experiments are not facts. The "argument from the taste of the child is childish," and that experienced men who are planting for profit will trust their own judgment before that of all the children in the world. (Exit).

Re-enter No. 3. He thinks discussing the flavour of Apples about as useful as discussing the beauty of colours. He thinks there is a muddle over the "Kings," and suggests the King of

Rea (not Rae) has not been grown, if seen, by the other actors, and that the variety sold as the King is not the King but Golden Winter Pearmain. Apples for quick bearing and cottagers should not be the same as for gentlemen's gardens, as poor men cannot afford to wait long for crops, but rich men can. The Ribston (not Ribstone) and the Blenheim he would not advise the former to plant, but gentlemen might plant them. Fine young trees of the Blenheim, about fifteen years old, at Chiswick, he says have not averaged a shilling's worth of fruit a year each, and Cox's Orange Pippin he pronounces the best dessert Apple in cultivation, but it does not bear so well in bad fruit years as does the Golden Winter Pearmain, which is sold as King of the Pippins. (Curtain).

Now, what can we plain people, who are unskilled in polemics, make of all that? What can the mixed readers of a general newspaper make of it? It seems to me to be a case of doctors differing, and may I add of doctors advertising? We are taught to believe that general editors are ultra cute men, but I am inclined to think some garden editors are cuter. If one can do the la-de-da, another take a burlesque, and a third a heavy part, and so get on the stage, we as amused onlookers must "clap" them all. I cannot for the life of me regard the business as otherwise than serio-comic. It seems comical enough to suggest that the Gravenstein Apple cannot be ripened in this country. Two hundred miles from London they ripen deliciously, but it is a gentleman's Apple. Equally funny is it to fancy the Newtown Pippin is worth growing in British gardens. In such it must be regarded as a curiosity. Rich, too, it must be to old hands who have tried the Ribston on different stocks for a good deal more than a generation to be told that it is to be cured of canker because a beginner is going in the same old track and thinks it new. I am not learned enough in the genealogy of pomology to give an opinion on the claims to kingship of two rivals, but I think I may venture to say that when a person advocates the planting of the Blenheim Pippin Apple for profit, he, at the same time, in my opinion, tells us as plainly as he can in a negative way that he has not planted any great number of trees and waited for their bearing. In these days of small profits and quick returns, the Blenheim with its good looks and fairly good quality, must steadily, but surely, decline in favour amongst planters of Apples for profit. Only men under thirty years of age can plant trees of it freely in confidence of realising a good return, while persons who plant after fifty may confer a benefit on the next generation, as it is only by chance that they will materially benefit themselves. As I have neither trees, books, nor papers to sell, nor anything to gain by posing as an authority, I must be content to remain in obscurity as—A YORKSHIRE-BITE.

THE SUNNY HILL VINERIES.

A RUN through the Sunny Hill Vineries, Littleover, Derby, is most interesting, showing what Mr. W. Innes has already achieved. His first three vineries date six years back—viz., three-span house 100 feet by 24. Two are planted with Gros Colman, the other with Alicante. This produced 23 cwt. of Grapes last year, about 1½ cwt. less this year. One house of Gros Colman was nearly empty. On tasting these Grapes, the greatest connoisseur could do no other than pronounce them deliciously refreshing. The other, still intact, was a sight never to be forgotten, containing eighty-two Vines, carrying twenty bunches to a Vine, averaging quite 2 lbs. a bunch. With all shoulders taken off the uniformity throughout was remarkable, there seemed scarcely a foot between the bunches. We could not help asking for a wrinkle, which Mr. Innes soon imparted. The borders were made entirely of turf cut from the land the houses stood on, to which a fertiliser was added. Last year the late Grapes were cut on the 15th March. All fruit hangs till marketed. Two lean-to's were erected and planted in the Jubilee year. The Vines were planted on the 10th August, and in seven weeks reached the top of the house. They have carried two crops, and produced 600 lbs. of Grapes the second year from permanent Muscats and temporary Gros Colman. The house is 70 feet by 16 feet. The other house is planted similarly. Steam power raises water from a well 80 feet to a tank elevated 30 feet. There is also a soft water tank the length of the building. The houses are well heated with two Trentham Cornish boilers and abundance of piping. I must add a word of thanks to Mr. Innes for so kindly explaining the details connected with his vineyard.—G. B.

GARDENERS OUT OF SITUATIONS.

I THINK "B." page 50, is on the right track when he makes a suggestion that gardeners ought to study their own interest more than they do by providing some remedy amongst themselves to lay the ghost of that ever present bogey, even to those who seem firmly fixed in situations—viz., the time when they are out of a situation; for, as "B." says, a hundred things may happen over which they have no control to bring about that undesirable event. The case of the gardener is much harder under those circumstances than that of the mechanic; the latter can take his kit to another shop in the same town, his loss only amounting to so many days or weeks, whereas the gardener must break up his

home and move into a cottage or apartments, as the case may be, and even when he gets suited he may have several hundreds of miles to go. All this packing and unpacking, loading, carting, and unloading of his furniture is a loss that cannot very well be estimated.

Independent altogether of finding a situation, why cannot gardeners who are in situations assist those who are out, no matter whether in the nursery or not? Surely there are always as many in places that the subscriptions would allow of, say, 10s. per week being given to those who are out. If more so much the better. Something of this sort would do good in two ways, first by staving off starvation, and secondly by making a man feel that he had friends working for him with a view to his being soon re-established. What is wanted is a central point or committee to start the thing, and I have no doubt the subscriptions will come in rapidly. I, for one, am ready when it is started.—H. B. W.

THE NATIONAL CHRYSANTHEMUM SOCIETY.

A GENERAL Committee meeting of the above Society was held in Anderson's Hotel Fleet St., on Monday, Jan. 27th. R. Ballantine, Esq., presided. The principal business was to consider the annual report and financial statement for the year 1889, and after some discussion it was resolved to recommend them to the annual meeting for adoption. The annual meeting was held at 7 P.M., E. Sanderson, Esq., in the chair, when the report and statement were formally submitted and adopted. The report reviewed the leading events of the year in connection with the Society, and referred to the preparations for the Centenary Festival of 1890, programmes and schedules of which will be issued as speedily as possible. The financial statement was very satisfactory, the receipts amounting to a total of £871 10s. 8d., the expenditure being £852 9s. 11d., leaving a balance in favour of the Society of £19 0s. 9d. It was subsequently stated that the reserve fund amounts to £100 19s. 9d., and the Centenary fund to £159 10s. The officers of last year were re-appointed, with Messrs. Crane and R. Cannell as auditors, and twelve members of the General Committee were elected in accordance with the rules. Several members having been elected and societies affiliated, the meeting terminated with a vote of thanks to the Chairman.

BIRMINGHAM GARDENERS' ASSOCIATION.

AT the fortnightly meeting, January 21st, Mr. R. Parker, Impney Gardens, Droitwich, had engaged to read a paper on the Chrysanthemum, but a severe illness prevented his attendance and the completion of his paper. What he had written was sent on to the Secretary and read, and a discussion followed in which several of the members took part, and it was a source of general regret that Mr. Parker was not present and his paper completed. Mr. Parker stated that he did not regard early propagation as absolutely necessary, some of his finest blooms being cut from plants struck in March, and this was done from old plants shaken out, planted under a south wall, and strong cuttings taken from these in March. Good turfy loam, with a sprinkling of bone-meal, and firm potting were recommended, avoiding heavily manured soil, providing copious waterings, and syringing in hot weather.

Damping and its causes were freely discussed. A general feeling prevailed that the damp mild weather had much to do with it, and that abundant bottom ventilation, with a little fire heat, was the best remedy for removing damp. Over-feeding was also regarded as another cause, and Mr. Parker evidently wishes it to be understood that he condemns such a practice. Cutting back plants and taking late cuttings with a view to obtaining smaller sized decorative plants were discussed, and Mr. Hughes, the Secretary, has adopted this plan with very great success, and stated that his plants were cut down in June, and he has had a fine display from the middle of November to the present time, but fortunately the early season favoured general success. For the future he intends cutting back all the plants the second week in May, as he does not want all the blooms at once, as he does not exhibit.—D. S. H.

VEGETABLE WHITEBAIT.

No doubt the readers of the *Journal of Horticulture* wonder what is meant by the above incongruous and somewhat "fishy" title. It is, I believe, quite new, but permissible, inasmuch as it is in accordance with precedent. Is not the "vegetable oyster" a recognised popular name as applied to a root grown in our gardens—Salsafy? And if vegetable oyster why not vegetable whitebait? But what is it—why all this preamble? Be patient—preambles are in accordance with precedent too. Was ever anything new introduced to the world without a preamble? Nothing.

Preambles are indulged in for creating a favourable impression, and so long as there is anything substantial at the end of them, are excusable. I fear, however, there is nothing very substantial at the end of this—but for the matter of that there is nothing very substantial in the real

Whitebait, yet the little mites of fishes are all the same enjoyable; so are the diminutive corkscrew-like tubers that were invested with the funny appellation at a family dinner the other day. "Oh, yes, we see what the prosy scribbler means, he is trying to say *Stachys*—*Stachys tuberifera*, but couldn't get it out without all this preamble." Exactly; the name is a bad table name, and people who hear it for the first time cannot get hold of it—cannot pronounce it, and when they do accomplish the feat there is no certainty they will not fail at the next attempt. Then they smile at the queer-looking things in the dish; sniff at them, fancy they are not good, perhaps have a suspicion they are not quite safe, and so a feeling of prejudice is raised against them. All this is true, there is not the least romance about it.

A short time ago a very good friend gave me a very good dish of tubers of this comparatively new vegetable. "Wash them well," he said, "boil them like Potatoes, then fry them in gravy or fat till a little brown, serve with melted butter or gravy according to taste, and you will find them good." And we did, but there was a little trouble over them. "Nasty lookin' furrin' things," the girl said, "they're like tight-laced maggots, an' I shall niver get 'em clean, niver." But she did, and they were cooked and served. "What do you call the funny little things?" asked the mater. "*Stachys*." "*What? say it again—spell it.*" It was now the pater's turn to be bothered; however, after a little mumbling he got it right. "Oh, very well, let me taste this *Stacky*, just one," said a sauey minx. "It isn't *stakky*," snapped another, "it's *stachis*." "No it isn't," chopped in a third, "it's *tubbiffera*." And all kept tasting and tasting, a little at a time, till at last the mater sententiously remarked, "You can call it what you like, I shall call it Vegetable Whitebait, and I think it's very nice!" Lucky hit. "Yes," struck up the chorus, "so it is, and it *is* like whitebait, do give me a good spoonful." "And me, and me," broke in the other youngsters, as if in fear there would not be enough to go round, but there was a piled dishful, plenty for all, and a little to spare.

At night, when supper was being spread, for we dine at midday on Sundays, a musical voice was heard, "Mary, bring in the cold Whitebait, please." It was brought in, eaten up with relish, pronounced as good cold as hot, and a hope was expressed that "the good man would send some more."

The name did it. As *Stachys* it would have been toyed with, and half of it left; as Artichoke it would have been thought common, and perhaps good enough to use in soups, but as Whitebait the brownish backed tubers were thoroughly enjoyed.

It is not a vegetable for the million, the yield is not heavy enough, and the digging and picking a little tedious; but if I had a good vegetable garden I should expect my man to plant some *Stachys* tubers at the same time and much in the same way as planting Potatoes, and next winter have a good supply of "Vegetable Whitebait."—A CITY MAN.

WORKING AND NOTING RESULTS.

GARDENERS generally have commenced once more a long and busy season with, it is hoped, the brightest prospects in view, and we trust successful results in store to crown their labours and anxieties. I say anxieties, because few gardeners escape these, however comfortable may be their position and circumstances, unless, indeed, they are indifferent to consequences; but those who are anxious to succeed do not take matters so easily, and to excel in their calling means one continual study and care, not only of matters under immediate notice, but also to be prepared for emergencies, which, as many truly know, often come upon them at dates and seasons most difficult to meet and carry out. Old practitioners can meet and readily overcome many difficulties, but not so the young beginner, and it is to such that these remarks are penned, and which, I trust, may assist many to cope favourably with some of the many dilemmas a young gardener often finds himself in.

The value of the working and carefully noting results can only be understood and appreciated by those who have adopted this useful and interesting practice, which when once earnestly taken up becomes a habit, and what a store of useful information is thus laid up for future reference and guidance. If young men would only note matters of interest during their journeyman and foreman days they would be laying up a harvest to draw from when placed in a more responsible position.

One of the greatest helps to a gardener is knowing how to time his crops. It is very annoying to find that on the eve of a large party, when he is expected to give a good display of his abilities, to find that a crop is past and the succeeding one not "in." Such things have occurred and do occur very often, but when notes have been taken for several years, and "timing" the different crops in their different stages, a sure guide is formed whereby one is able to turn and work accordingly to produce his crops to suit any occasion, presuming due notice has already been given. Thus it will be seen, that supposing a grand display of forced plants and cut flowers is required for a certain date, a properly kept note book ought to tell the grower how long say it would take Lily of the Valley or any other plants to fully develop after being placed in a certain temperature.

The same remarks hold good of fruit growing, with the exception in one sense of Grapes, which so long as they are ripe can be used when wanted. Even with Vines records ought to be kept of the time, under different temperatures, the different stages of growth occupy from "breaking" to flowering, flowering to stoning, and from stoning to ripening. It is, however, more with such crops as forced Strawberries and Peaches, fruit that will not keep any length of time, that requires the closest attention, as the different varieties are subject to a wide margin in "turning in," and it is only by noting these differences in varieties under diverse conditions and treatment that any true criterion can be formed. When once grasped the grower is master of the situation, and he goes on with his undertaking with the full knowledge that he is adopting the proper method to ensure certain results, and seldom are such men wide of the mark, and their study of "timing" forms no mean part of their cultural skill.

It is not so with the cultivator who has never thought this worth looking after, and merely trust to his experience, which in some cases is not very large. When called upon to meet certain requirements at certain dates he finds then the want of a record to work on. Work under such conditions becomes a great anxiety to him, with the result that he worries himself and those about him, first from the fear of being too early, the next day, perhaps, from fear of being too late, and regulates the temperature accordingly, thereby trusting chiefly to good fortune to fulfil what he lacks in knowledge.

I know no occupation more interesting than noting different subjects under different treatments and conditions, such for instance as in Pine growing, how these one season vary or correspond to another in the time of "showing," flowering, and ripening. Melons, too, are worthy of notice, and it is surprising to find how these vary, according to the season, in the time from setting to the ripening period.

My remarks have been chiefly with plants forced under glass, but the same interest should be shown in kitchen garden crops generally, in fact more, as season and situation affect these more than the others. Many crops fail through the seed being sown at the wrong date, such as Celery "bolting" through being sown too early in one district though the same date might suit another. Spring Cabbages not standing the winter or not turning in as early as wished, generally proceeds from the seed being sown at the wrong time. It is the same with many other crops, which if their failures or the opposite were carefully noted would save many disappointments, while it would make work more pleasant and do away with many of a gardener's anxieties. I have practised it and proved its value.—R. PARKER, *Impney*.

CATERPILLARS AND FRUIT TREES.

In a somewhat elaborate article on "Enemies of the Apple and Pear," published in the Fruit Conference issue of the Royal Horticultural Society's Journal, several insects and their work are illustrated; but singularly, what is probably the most destructive pest of all, is not mentioned either by the author or in the discussion that followed the reading of the paper at Chiswick last October.

We allude to what is popularly known as the winter moth, or, scientifically, *Cheimatobia brumata* (Stephens).

On page 39 Mr. S. T. Wright of Glewston Court referred to this scourge

FIG. 16.—THE WINTER MOTH.
Winged male, wingless female, and caterpillar.

of the garden and orchard as follows:—"Probably the greatest drawback in fruit culture is the caterpillar plague. Last year the damage done was immense, and this year I fully expect an even worse attack

unless something unforeseen occurs. Fruit trees, forest trees, and hedges are thickly studded with the eggs of the winter moth; and though we had a splendid autumn for fruit trees, ripening their wood and perfecting the fruit buds, the outlook is decidedly gloomy. The person

FIG. 17.—EGGS OF WINTER MOTH.

A, shoot natural size, with eggs on bud; B, stem natural size, with eggs in the end; C, the stem increased 5 diam.; D, egg magnified 30 diam.

who can invent a certain remedy for this pest will deserve a country's gratitude and a well filled pocket."

The winter moth (fig. 16) is so named because of emerging from pupæ in the ground in October or November; at least the male insects are usually seen flitting about in the twilight then, for their habits are nocturnal. Only the male, which has a yellowish grey body and ashy grey wings, can fly, the female having only rudimentary wings, useless for purposes of flight. The egg-laying insects crawl up the stems of trees, and thousands have been caught by hands smeared with adhesive mixtures, but these have not always been effective. Whether through being applied too late, or whether there is some other method of ascent, is not known, but it is certain trees that have been bandaged had every blossom and leaf stripped off them in May and June.

Authorities, who copy one another with more or less fidelity, tell us the eggs are deposited on twigs, buds, and in crevices of the bark. That is so, no doubt, but, as Mr. S. T. Wright pointed out last year, infinitely more are packed away where they have been little suspected—namely, in the ends of the shoots or cuts left in pruning. A slight shrinkage occurs there, and interstices are thus formed between both the outer and inner layers of the bark. These our correspondent, we think has proved, are the favourite resting places.

He recently sent us a number of twigs and snags cut from the trees under his charge, and in every sample there were a hundred times more eggs in the cut ends than on the buds or the bark. Two of these portions, one (A) with eggs on the bud, the other (B) with eggs in the end of the stem, also under a spur—the arrows pointing to them in each case—were sent to Mr. W. G. Smith for engraving, natural size, with an enlargement of the stem (C) for showing the eggs more clearly; some of them (D) he has also enlarged considerably. There is no mistake about them, nor of the place of concealment that is depicted with exactitude in the figure.

The discovery of our correspondent—for such, we think, it may be fairly regarded, and now for the first time made visible to the world—is a step in advance in knowledge on a subject of very great importance. He now wishes to know how to destroy the myriads of eggs, and intends making experiments to that end. We can, however, tell him how to destroy the bulk of them, and we hope he will try the simple method

very carefully with some trees if he cannot on all, for we believe he has a few thousands to attend to. It consists in the prosaic work of pruning the trees again, cutting off the end of every shortened shoot or snag, young or old, that can be removed with a knife, and taking particular care that the nests full of eggs are burned. It is not very likely the mites of caterpillars that may hatch from eggs, which may perchance fall to the ground, could ascend the trees, but when risks can be avoided it is better to avoid them. The eggs will not fall out of their positions during the pruning, but the severed nests may fall accidentally.

Trees pruned again at once as suggested, and further washed with a petroleum, arsenical, or other solution that may be hoped to spoil the eggs on the buds and branches, ought to be comparatively free from caterpillars in the spring; for disposing of the foe that may emerge when the blossoms are expanding and young leaves unfolding we know of nothing safer to use than a solution of hellebore.

MOSS ON LAWN.

YOUR correspondent "G. B." will derive much good by treating his lawn as you advise (page 78) for the destruction of moss, but it may only be temporary, and if his soil is of a clayey nature, draining of itself will perhaps not accomplish the desired end—at least we have not found it so. The fact is, lawns are necessarily subjected to most irrational treatment. They have often to be rolled and mown when very wet, and as a consequence the soil becomes puddled, and the pores stopped, thus preventing the water percolating through to the drains. We well drained our lawn six years ago—2-inch pipes were laid into a 3-inch main, the former 2 feet 6 inches deep and 6 yards apart, the latter 3 feet deep, and the drains were filled to within 1 foot of the surface with rough ballast. We can, however, and have this winter, raked off moss by the cart-load.

The best way to kill moss on lawns is to pare up the turf and dig, or, better still, bastard trench the ground, working in at the same time a quantity of gritty matter if the soil is of a heavy nature. As soon as the weather has sufficiently fined down the surface, and it is sufficiently dry, the same turf can be relaid however mossy it may be, for it will sure to disappear the first season, and the finer grasses will abound. We did part of our lawn after this manner four years ago, and there are now no signs of moss. The growth is fully a month earlier, and the yield of grass double that of the part not so treated.

Young gardeners should take note of this, for it undoubtedly proves that earliness and fertility do not always depend upon geographical position and unlimited manure, but on the healthy mechanical condition of the soil. Mossy lawns treated as above can be made much firmer with less rolling—a circumstance which lawn-tennis players will appreciate.—J. H. W., *Leicester*.

HARDY FRUIT GARDEN.

IMPROVING ORCHARD TREES.—Although comparatively young trees, or those that have not long since arrived at a good bearing state, are likely to prove most profitable in the end, especially if the selection of varieties is a judicious one, it does not follow the older orchards will not pay for any further attention; on the contrary quite the reverse holds good, large old trees of Blenheim Pipin, Warner's King, Beauty of Kent, Reinette de Canada, Tower of Glammis, and others that might be named not unfrequently producing really valuable crops. In any case the larger and more perfect the fruit the more valuable is the crop, even if only devoted to cider making; therefore freely thin out the branches in all instances where they are much interlaced, the aim being to admit as much light and air to those reserved as possible, even if this does necessitate the removal of two or three large faggots of wood from a single tree. Not unfrequently orchard trees have overgrown each other, and the more worthless of them ought therefore to be cut clean out, or all should have the straggling main branches well shortened back. In after years a little timely thinning will obviate the necessity of this wholesale pruning, and an improvement will soon be manifested in both the quality and weight of the crops borne by trees thus well attended to.

STUNTED AND MOSSY TREES.—In low-lying positions and clayey subsoils the trees of Apples especially are liable to become stunted and covered with lichen and moss. Improving or renovating the system of drainage will sometimes do much towards recovering the trees, but it is not an infallible remedy, and on the other hand may easily be overdone, too little moisture left in the ground being almost as bad as having too much at certain parts of the year. A deep 3-inch pipe drain in the middle of every second clear space between the trees ought to be sufficient, and if it is seen the old drains are choked by tree roots it will be found cheaper and better to lay quite new drains rather

than search out and restore the older ones. Forest trees, notably Elms, are a great nuisance near an orchard or garden, their roots penetrating to a great distance, and soon choke up any drains they find their way into. The good old plan of well scrubbing the stems of Apple trees with a stiff brush or broom and rather strong brine is yet the best for temporarily removing moss and lichens, and thoroughly coating the affected portions with lime or strong limewash also answers well, but neither are thorough cures unless superfluous moisture is drained off.

FRUIT FORCING.

VINES.—*Early Forced in Pots.*—Afford copious supplies of tepid liquid manure to Vines in pots. Thin the bunches somewhat freely, so as to induce large berries, not, however, making the bunches loose, though that is better than small-berried clusters. The temperature should be maintained at 65° at night, falling to 60° on cold mornings, 65° to 70° by day, admitting air at 75°, increasing the temperature with the sun heat to 80° or 85°, closing the house at 80°, with a prospect of an advance to 85° or 90°, at the same time damping the house. Damping is also necessary in the early part of the day. Great care is necessary in ventilating. During sharp weather admit air moderately, so as not to reduce the temperature much, but to prevent its rising suddenly.

Earliest Forced Houses.—The earliest Vines require careful attention now. Remove all loose and duplicate bunches, thinning the berries as soon as they are well formed. If there are no fermenting materials in the house, charge the evaporation troughs with liquid manure, but not urine, or 1 lb. guano dissolved in twenty gallons of water, and the borders may be sprinkled when closing the house, or early in the afternoon. Where results are of more consequence than appearance a portion of the fermenting materials may be removed and the whole of the inside border surfaced with manure from the stables, which must be turned several times before it is introduced, or the ammonia will be too strong for the tender foliage. The inside border, before being covered with the manure, must have a good supply of water, tepid, but not exceeding 90°. This, with the leaves in an active state, will incite root action, and the berries will swell freely. Avoid cold currents of air, also steam arising from highly heated pipes, both being prolific of rust. The heat of fermenting materials on outside borders must not be allowed to decline, but should be renewed as required. Where no fermenting materials are used care should be taken to prevent the roots in outside borders becoming chilled by cold rains or snow, having wooden shutters or tarpaulin so disposed as to throw off the rain or melted snow. Attention will be required in tying the shoots and in stopping the laterals. It is assumed the shoots have been stopped two or more joints beyond the fruit. Where the space is restricted they may have been pinched to one or two joints, and in any case the auxiliary growths may be rubbed off except from the two lowest leaves, those above the fruit being stopped to one joint. It is of the utmost importance that the principal foliage be fully exposed to light and air, therefore stop the auxiliary growths at the first joint; at the same time very close stopping is not to be recommended where there is room for extension, as an increase of foliage promotes corresponding root action; therefore preserve all the foliage consistent with its full exposure to light, overcrowding and overcropping being highly prejudicial.

Houses in which Vines are in flower should have a steady night temperature of 65°, 70° to 75° by day by artificial means, and 5° to 10° more from sun heat. Muscats 5° higher all round. Black Muscat and other varieties liable to set indifferently may be assisted by tapping the bunches every day, or more certainly by applying ripe pollen, drawing a brush lightly over the bunches. A constant circulation of dry warm air is conducive to a good set, and it is advisable not to stop the growth closely during the setting period.

Vines Started Early in the Year.—Syringe the roots twice a day until the bunches are formed, when it is best discontinued, but maintaining atmospheric moisture by damping the paths and borders three times a day. Increase the temperature to 55° at night and 60° to 65° by day, with an advance from sun heat to 75°, with ventilation in accordance with the state of the external air. Avoid damping the hot-water pipes when they are highly heated, the steam arising therefrom being very different from that given off by cooler surfaces. Keep up a supply of ammonia in all the houses by turning the fermenting materials and adding fresh horse droppings; or if that be objected to the house may be sprinkled with liquid manure, the evaporation troughs being filled with the same. Ammonia vapour not only aids the growth and texture of foliage, but is inimical to red spider.

Houses for Affording Ripe Grapes in July.—Start the Vines not later than the beginning of next month. There is no need to cover the outside border with fermenting material, but a covering of leaves or litter is necessary to prevent chill. A bed of fermenting material inside the house conduces to a good break by securing a uniform moisture. Syringe the rods three times a day, maintaining the temperature at 50° at night and 65° by day with sun heat. Water inside borders with liquid manure at 90°, and repeat as necessary, so as to bring the soil into a thoroughly moist state.

KITCHEN GARDEN.

THE WEATHER.—Owing to the continuous and excessive moisture of the soil, we have not been able to dig or trench much lately, and these operations must be pushed forward as soon as circumstances will permit.

SOUTH BORDERS.—These are the best of all positions for the earliest vegetable crops, and when they are well drained and fertile they will

produce crops ready for use several weeks before the main quarters. The soil should be thrown back from the front to form a good incline, adding fresh soil if necessary for securing the desired advantage.

CARROTS.—Those sown in frames on hotbeds are showing through the soil, and a little air must be admitted on fine days, as it is a great mistake to allow them to be drawn at first. So soon as they can be handled thin out the surplus plants, but only sufficiently to allow the others to form roots for drawing for early use. Another frame may be sown to succeed these, and early in February, when the soil on the south border is in good working condition, sow a few rows or a bed there, using seed of Early Horn variety in each case.

POTATOES.—Those in hotbeds are pushing strongly. We admit a little air on all favourable occasions, and place mats on the glass every night, whether it is frosty or not, as the plants are so delicate that any neglect in this way might ruin the crop. The soil in which they are growing must be kept moist, but not too wet. More may be planted on other beds, and it will be found that these will make rapid progress, and may in the end equal those planted several weeks ago. Tubers intended for planting in the open for the first crops should now be spread out in a suitable place to induce the formation of robust shoots.

PEAS UNDER GLASS.—We do not raise many Peas in pots on turves, as we find sowing in favourable positions in the open ground answers our requirements. However, all have not favourable positions who desire very early Peas, and these should now make a good sowing in pots under glass, with the object of securing healthy plants for transferring to the open ground in March.

CAULIFLOWERS.—Stir the surface of the soil between the plants that have been in frames and under handlights since last autumn, and water them with liquid manure, to induce the production of new roots before planting them out. Seed of the earliest varieties may be sown in shallow boxes and placed in a gentle heat. We raise many plants in this way, and often find them as early as the others and better.

PLANT HOUSES.

Crotons.—Large heads that were rooted in August, wintered in 6 and 7-inch pots, and intended for growing on, may be placed into 10-inch pots. Do not disturb the roots further than is necessary to remove the old drainage. The pots should be liberally drained, and the soil pressed firmly into them. Young stock that has been preserved in various sized pots for decorative purposes may now be potted. If possible plunge the pots in a bed of litter and leaves, the gentle bottom heat they will enjoy will soon start them into root activity and growth. The syringe may be used lightly once or twice daily, according to the weather. Supply carefully with tepid water until the plants are rooting freely in the new soil. Crotons do well in a compost of fibry loam, sand, and one-seventh of manure. A 6-inch potful of soot mixed with each barrowful of loam will prove beneficial to the plants. Before potting be careful to place the soil in some position where it can be thoroughly warmed. Pot the plants in the house in which they are to be grown. Too much care cannot be taken to prevent their receiving a check. Where a close frame and brisk bottom heat can be supplied, cuttings in quantity according to demands should be inserted without delay. Be careful to take the cuttings where the wood is thoroughly soft. Cuttings with a moderately soft base root in one-third the time that is the case with those that have firm wood. The cuttings will also root without losing a single leaf, but when the wood is firm at the base, nearly every leaf will fall before the cuttings are rooted.

Marantas.—Where division of these plants or the reduction of large plants is necessary the work should be done at once. These plants dislike strong sunshine and must be repotted early, so that they will become thoroughly established before the sun gains much force. The plants have then a long season's growth before them. Drain the pots liberally, and render the soil open and porous by the addition of sand and charcoal. Some kinds do well in fibry peat, others in loam, but the majority succeed in a mixture of both, with charcoal and sand added, or the addition of broken crocks. Strong-growing Marantas of the zebra type succeed in fibry loam, a little manure, charcoal, and sand. Plunge the pots in brisk bottom heat, where the atmosphere is moist and the temperature ranges about 65° at night.

HINTS FOR BEGINNERS.

THE WEATHER.

AFTER ten days of extremely wet and stormy weather we have had a fall of snow with a temperature of 14° Fahrenheit, the lowest record of the season. For some days previous to the fall of snow the temperature fluctuated greatly, running from freezing point to 52° in an hour's time, which is always sure to occur when the elements are so disturbed as they have been since the end of December. The effect such storms have had on the bees was to bring them out when the temperature rose. When calm no loss of bees occurred, but when windy some never returned. This was

more noticeable with bees located in hives with solid projecting floors than in ventilated ones. Such hives are now in a thoroughly saturated condition, which creates cold and is fatal to bees, and makes them restless, consequently dwindling hives. All hives of such a nature should have their floors immediately changed, and the hives, which are sure to be damp, thoroughly dried, or the frames with bees transferred to clean and dry hives. All hives having wide entrances will be found to be the dampest.

SWARMING V. NON-SWARMING.

About thirty years ago the advantages of non-swarming hives were fully explained, while recently considerable attention has been paid to them, and all that was of value to the bee-keeper and beginner made clear. Swarming can only be prevented by introducing a young and fertile queen at the proper time, taking care that ample breeding room has been provided. Bees will swarm from a hive not more than one-third full, but I need not take up space in repeating what was made clear so lately in these pages. "A Howdenshire Bee-keeper" says, "Some bee-keepers have tried the non-swarming system, and failed simply because they did not attend to the wants of the bees in time to prevent the desire to swarm."

Giving room in time appears to be the means adopted by your correspondent. The plan may succeed for a time when under-sized hives are used, but will not when non-swarming hives are of the proper size. Adding supers in any case is not the proper thing to do, but more breeding room, and unless worker comb is provided drone comb will be built, which will only hasten what we wish to prevent, and this in some cases when foundation has been given.

Scarcely a season passes without some of our non-swarmer swarming, but we do not mind this, as an interchange of partly filled supers and some of the frames from the stock to the swarm puts all right, and then swarmers always give the greatest results when we have a prolonged season. The past year was no exception to non-swarmer swarming, particularly at the Heather, where taking it all round 70 per cent. of the hives swarmed, and yet every one of these was provided with ample room in good time, but swarmed notwithstanding.

YOUNG QUEENS.

Apropos of the above a query has been addressed to me, "What is the best kind of queen to keep to increase swarming?" I replied that a youthful queen was certainly the best for swarming purposes. This answer provoked another query, "How can I reconcile the statements that young queens are best for both purposes?" My reply was that bees only prepare to swarm when breeding does not go on in accordance with what appears to be their desire, therefore a young queen having plenty of breeding space meets the bees' desires, and royal cells are not formed. On the other hand a young queen is the best stimulative of bees, and young bees are brought forth in greater numbers, filling the hive more quickly and earlier than where there are aged queens. The swarms, too, are larger provided extra room is not given to a moderate-sized hive; but after a queen has laid constantly for months she does not deposit so many eggs, and this may be the sign for bees to raise successors. There is nothing paradoxical in this, and the beginner should bear all that in mind, and keep a constant watch upon all non-swarming hives, or some day when least expected, and when the expectation of a harvest is high, they will swarm.

THE LANARKSHIRE HIVE.

In reply to "J. D. L., Northumberland," it may be said that it is immaterial whether the top bars be 14 $\frac{1}{2}$ or 14 $\frac{3}{8}$ long. The main thing to be guided by is the size of the hive, which should be square, having nine frames spaced at 1 $\frac{1}{2}$ inch apart from centre to centre, having the outer spaces a quarter inch wider, 14 inches being the exact size inside. The rebate to receive the frames is the same as the check in the ends being nearly $\frac{1}{4}$, leaving fully three-eighths

of a lip, the ends being three-sixteenths longer a bottle or head is wrought upon the ends, which gives a neater appearance and saves the planing of the wood after it is nailed. The sides are cut one-sixteenth longer than the top bars; this gives the necessary slack, and if a gauge is used for working both sides and bars, and neatly cut, there will be a proper fit of all the pieces.

Let the end pieces, or hangers to the frames, be five-eighths of an inch clear from the bottom, but have no bottom rail; that in shallow frames is unnecessary, it takes up room, the bees seldom building their combs to it, and the bees are more liable to soil their combs with than without bottom rails. With deep frames it is different. Elsewhere it has been stated that dispensing with the bottom rail was a retrograde movement. Had the author of these words visited us when in Scotland lately he would have been convinced to the contrary, and gained other useful lessons besides. It would be very interesting to know when the British Bee-keepers' Association adopted the standard hive, disallowing other sorts to compete at their shows, and then ultimately to adopt a shallow frame, where the retrograde movement came in.

The divisions are $6\frac{1}{2}$ inches deep, and allowing half inch for the top bar, measure 6 inches inside, the front being half inch less, this is the doorway. A pair of five-eighths match ploughs are the proper tools to groove the front and tongue the slide, which should be half an inch broad, running the whole width of the hive. I use the same sort of box, and same size as the body ones for sections, when nailed to top bar, when held in angled tins a half inch shallower. For a full strength hive two divisions do very well for small supers, but I use one 9 inches deep in addition to an extra $6\frac{1}{2}$ one, this gives space for three rows of supers, and 3 inches for packing above. Yellow pine is the best wood for hive-making, allowing the escape of moisture more freely than white pine, only used within the past fourteen years or so on the pretext that hive makers were charging an exorbitant price, but in reality the white pine hives are the dearest and least satisfactory in the end, having cheapness only for its recommendation. Yellow pine hives, or other articles made from it, will wear white pine goods many times over, and where price is no objection should be used.

BEES HYBERNATING.

I hope "A Hallamshire Bee-keeper" does not think I am opposed to his method of queen-rearing. I am perfectly confident that queens reared on the lines he lays down are superior to those obtained by some, but I fail to see that bees hybernate during winter. The 12th of January he speaks of was fine here, and the Punic bees I had from him were working on the Arabis and every hive flying, and on the day after, the lowest temperature for the season, many bees showed themselves outside. How is this if they hybernate? I quite agree with him that progress should be the motto of all, not only with bees but with everything. I certainly do not think that my methods of managing are perfect, but I do not hesitate to say that what I have taught is ahead of most bee-keepers. This is proved by the simple fact that both in this country and on the Continent they only follow instructions taught by me years ago. This "A Hallamshire Bee-keeper" well knows, as I also know that some of his ideas are claimed by bee-keepers both in this country and in America. Fate may in due course put these matters aright, but neither of us will be prevented giving useful information in the future which may crop up, and which our experience enables us to give upon a reliable basis.—A LANARKSHIRE BEE-KEEPER.

P.S.—Bee plants in flower are Arabis, Wallflowers, and Primroses, also Hellebores, Aconites, and Snowdrops.

TRADE CATALOGUES RECEIVED.

J. & R. Thyne, 83, Vincent Street, Glasgow.—*Descriptive List of Garden Seeds.*

Hooper & Co., Covent Garden, Maida Vale, and 83, Regent Street.—*Seed Catalogue, 1890.*

J. Lambert & Son, Treves.—*List of Seeds.*

Leonard Coates, Napa, California.—*Catalogue of Fruits and Trees.*
James Yates, Underbank, Stockport.—*Catalogue of Carnations, Picotees, Pinks, &c.*
Brnant, Poitiers (Vienne, France).—*Catalogue of Plants.*
W. Tait & Co., Capel Street, Dublin.—*Select Annual List, 1890.*
Hogg & Wood, Coldstream-on-Tweed.—*List of Garden Seeds.*
G. Stevens, Putney.—*Catalogue of Chrysanthemums.*
Merryweather & Sons, 63, Long Acre, London.—*List of Watering Hoses.*

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Turfy Soil (F. C.).—The value of turf for purposes of cultivation depends on the nature and quality of the soil from which it is cut.

Grass Seeds (E. B.).—If you state your requirements to your seedsman you will be supplied with a suitable mixture for the purpose in question.

A Cheap Book on Orchids (H. T., Frome).—The information you require is contained in Mr. Lewis Castle's book on Orchids, published at this office, post free, 1s. 2½d. You have been rightly informed, and you should have no difficulty in successfully managing a small collection. Orchids, however, like other plants, require constant attention, and if you encounter unexpected difficulties we will gladly assist you with advice upon any point.

Unfruitful Pear Tree (J. F. W.).—Has the tree been planted too deeply? If there are few or no fibrous roots near the surface fork away the soil down to the larger roots and for a distance of 3 feet from the stem, and add in place of it a mixture of good loam, decayed vegetable matter, and wood ashes—as many of these as you like—press down firmly, and surface with littery manure, thick enough to prevent the sun drying the fresh soil in summer. New roots will then take possession of the added compost, and the tree will improve in health and fruitfulness.

Improving Lawns (J. W., Ryde).—A mixture was named on page 78 last week for applying to lawns now with the view of improving them, and will do good whether there is moss in them or not; but drainage is often needed when the soil is of a clayey nature. When this and the dressing fail to improve the verdure a method that has been found very successful is described by a correspondent on page 96 of our present issue. A hundredweight of bonemeal added and a bushel of soot to each cartload of the mixture would improve it considerably, and if you have not enough for dressing both lawns apply what you can to that on chalk, and give the other a dressing of three parts of superphosphate of lime and one part sulphate of ammonia, at the rate of 5 cwt. per acre, or 2 ozs. to each square yard. The sooner the applications are given the better. Making lawns black with soot on a showery day also improves the verdure. If there is no Clover in the grass and you want some apply two parts superphosphate, one part each of kainit and sulphate of ammonia.

Violets in Frames (J. H.).—The method which you have been instructed to adopt of "planting single runners of Violets in cold pits in October" is not the best for affording a good supply of blooms in winter. We have seen stout runners with good crowns inserted an inch or two apart in boxes of light soil kept moist in a warm light house afford blooms plentifully in a few weeks, but no such results could follow in a cold pit. Only failure could be expected by the plan you describe, but as you acted "under orders," obviously the fault does not rest with yourself. Rooted offsets should be planted in good soil in the open air in April, the runners suppressed, red spider subdued, and strong plants with bold crowns will be produced by autumn for establishing in pits or frames before winter for flowering during the dull months of the year, the supply largely depending on the weather when no heat from fermenting materials or otherwise is afforded. A hundred times more flowers will be produced by this method than by the one you have been instructed to carry out.

Peach Buds Falling (X. Y. Z.).—Our reply to a correspondent on page 78 is applicable to your case. The wood you have sent is not ripe, and the trees have made a disproportionate extent of strong and comparatively fibreless roots in the too deep, probably too close, and possibly too wet border. We also notice you refer to scale, and if red spider should also have been present, the insects have had their share in contributing to the misfortune. The time has arrived for a large proportion of the old soil being taken away and fresh added, in which the roots can be spread for the production of fresh fibres. Whether this is done now or in the autumn, before the leaves fall, can only be decided according to the circumstances of the case—the present condition of the trees, and requirements. As they are not likely to bear any fruit this year, or if a crop can be dispensed with, we should set to work at once in border renewal. A depth of 2 feet of firm soil is ample for Peaches, and some of the best of trees and crops are grown in borders a little shallower than that. We should also train the growths more thinly, and do all that is possible to secure well matured wood. Then with a mass of fibrous roots in good soil, the buds will be retained under proper routine management, as indicated in our "Work for the Week" columns.

Grapes Shank (*Idem*).—We have seen much worse wood than the sample you send, and if the laterals are thinly trained and half of the inside border removed, forking out some of the soil that appears inert even nearer to the stems, and add sound loam containing wood ashes, rubbish, and a sprinkling of bones for encouraging the production of fresh roots, good sound Grapes should follow, always provided the crop is not too heavy for the Vines to perfect. The number of bunches does not enable us to judge on that point, as some are thrice the size of others, and it is the weight that tells. With the rods $2\frac{1}{2}$ feet asunder the laterals should not be less than 18 inches apart up each side, or the foliage will be overcrowded. The border, we suspect, is too close and not so sweet as it should be, and fresh roots are wanted in fresh soil for improving the Vines and Grapes.

Lapageria Unhealthy (F. G. W.).—There are two main reasons why these plants are often in an unsatisfactory state in pots:—1, Close, soil not sufficiently drained, and hence sour. 2, Pots so densely crowded with roots that the plants do not receive adequate support. Lapagerias usually grow best planted out in a bed at least 18 inches deep, the bottom 6 inches being of drainage, broken clinkers and charcoal being excellent, the remainder springy turfy peat and loam, twice the quantity of the former, with a liberal admixture of charcoal, the whole to be pressed down as firmly as the turfy nature of the compost permits. A bed thus prepared can scarcely be made sour, due provision being made for the free exit of water from the drainage, and when the soil is permeated with roots it is not easy to give too much water; until then water must be given more sparingly, yet the soil should never get anything like dry. If you prefer growing the plant in a pot, prepare the soil similarly. In the event of your plant not having rooted freely, it will be advisable to remove a good part of the old soil, which will be sour, and give fresh as suggested, thinning out and shortening wiry growths to the best buds you can find, syringing the plant twice or thrice a day according to the weather, to prevent excessive evaporation from the leaves, and so assist the emission of fresh healthy roots, which alone can invigorate the plants. We know of Lapagerias that grow luxuriantly and flower profusely on the north side of greenhouses.

Potting Begonias (L. S.).—It is not too early to pot them provided you have a suitable position for starting them into growth, such as a heated pit or propagating house. They should be potted in a compost of equal parts of loam, peat, and leaf soil, with a free admixture of silver sand, each tuber being surrounded with sand and placed in the centre of a small pot. If the pots are plunged in cocoa-nut fibre refuse or sawdust of a temperature of 75° to 80°, it will be of great assistance to them, as if the plunging material is kept moist it will not be necessary to water the soil in the pots—a point of some importance, since, unless the greatest possible care is exercised in applying water to the tubers, a number of them will decay. The soil should be moderately moist when used, and the temperature of the house be kept at about 70°. When growth commences raise the pots and place them on the bed for a few days, then remove them to a shelf near the glass, and as soon as the roots can be seen protruding through the drainage shift the plants into larger pots, and grow them in a light position in a house having a minimum temperature of about 60°. When artificial heat cannot be afforded to the extent and in the manner indicated, the tubers must not be potted so soon. If they have to be started in an ordinary greenhouse, the middle of April will be soon enough for potting; if, however, they are established in pots in which they were grown last year, it will be a safe plan to allow them to start in these pots, shaking them out carefully and repotting when the growth is half an inch long. A hotbed, such as a Cucumber frame, will then be of considerable assistance in the early stages of growth, but they must not remain in such a frame to be drawn up weakly.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (W. B.).—1, Flanders Pippin; 2, Winter Colman; 3, not known; 4, Curl Tail; 5, not known; 6, Golden Winter Pearmain.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers.

Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (H. J.).—1, An excellent variety of *Cœlogyne cristata*; 2, *Dendrobium nobile*, very little inferior to *nobilis*; 3, *Odontoglossum Pescatorei*. (W. R. S.).—1, *Adiantum pedatum*; 2, *Adiantum farleyense*; 3, *Adiantum trapeziforme*; 4, *Goniophlebium subauriculatum*.

Moving Bees (H. S.).—Much injury is done to hives by moving them from one place to another in the home apiary, and the more chilly the weather is the more bees are lost, although not seen. Bees may be moved from one place to another if not exceeding the distance you name, and one hive at a time or in a day, provided it be gradually moved, leading the bees as it were, and the day warm, not otherwise. For example, when bees have been taken from a chimney or tree, and put into a hive with their queen, after she is missed from the original spot they will follow up the hive to wherever it may be set, just as a swarm will do. On the other hand some people tell us to make a swarm strong, place the old stock a little to the right or left of its original site, and set the swarm on its site, and the stock bees will join with those of the swarm. They will do nothing of the sort, but will search for their old hive and enter it, raising a hum at the time, and act as if they were crying out, "This is our home, come to it." When this is wanted the old stock must be moved a long distance away or taken within doors, and even then we have witnessed the bees find it out. Just try some of these experiments, and you will soon learn how silly such teachings are—moving bees short distances and placing branches near their hives to indicate the place to return.

COVENT GARDEN MARKET.—JANUARY 29TH.

No alteration.

MANURE FOR CEREALS AND ROOTS.

THE best crop of roots we had last year was in a twenty-acre field, half of Mangolds and half of Swedes, at the home farm. The Swedes were after Rye, after Barley; the Rye was folded by ewes and lambs, the trough food consisting of crushed Oats and Mackinder's Lamb Food. The Mangolds were after the same crop of Barley, but as no Rye had been sown on that part of the field, deep furrows made with the double-breasted plough were filled with farmyard manure, carted direct from the yards to the furrows, and covered at once by passing the plough along between the rows, and the ridges were pressed slightly with light Barley rollers both before and after the drilling. This, we may explain to beginners, is termed sowing on the ridge. The Swedes were sown on the flat. No chemical manure was used, but a full dressing of it had been used for the Barley, and the residue, in combination with farmyard manure for the Mangolds and sheep manure for the Swedes, was sufficient to produce one of the best crops of roots we ever grew. No doubt a favourable season and early sowing contributed materially to the final result, but that could not have been nearly so favourable without an ample store of fertility in the soil, and the point we wish to mark especially here is the value and kindly influence of such residue.

It is a golden maxim in farming never to exhaust the soil of fertility, but to replace that taken from it by the cropping of the year by at least an annual dressing of some manure. It was once thought that chemical or artificial manure was only useful for the crop to which it was specially applied, but it has been proved repeatedly beyond question that there is always a residue in the soil after the crop is matured, if a due proportion of mineral manure was used in combination with the indispensable nitrogenous manure. As to the loss of nitrogen in winter, no good can be done by laying undue stress upon that fact, and we are positive that an autumn dressing sown with Wheat, Rye, and winter Oats proves highly beneficial. The Wheat and Oat plant is always much more sturdy and vigorous when the manure is drilled with it, and the Rye is so vigorous that we can always depend upon an early growth for folding, no matter how backward the spring may be. It is impossible to realise the wide difference which manure or no manure makes to Rye unless it is fairly tried out, and we are quite within bounds in saying that with manure the first growth is ready for folding a fortnight earlier than it is without it. Only a hundredweight per acre is required for drilling with the seed, and it consists of half a hundredweight of nitrate of soda, quarter of a hundredweight of steamed bone flour, and a quarter of a hundredweight of mineral superphosphate. Anyone having a backward crop of Rye now on poor land would do well to give it a surface dressing of a hundredweight of nitrate of soda per acre early next month.

A safe mixture for drilling with spring corn consists of 1 cwt. nitrate of soda, $\frac{1}{2}$ cwt. muriate of potash, $\frac{1}{2}$ cwt. superphosphate, $\frac{1}{2}$ cwt. steamed bone flour. This may also be used as a surface dressing for winter corn. Oats have been low in value for some time now, but really good British Oats always command a special price, and if Oats are grown at all it certainly answers to use the best samples of seed, and to manure just as highly as for Barley. There can be no doubt that the average yield of Oats is much below what it ought to be. It is possible to grow twenty sacks of Oats per acre, and if the grain is thick, plump, and heavy, weighing from 40 to 45 lbs. per bushel, it should find a ready market at 10s.

per sack, which price gives a total superior to that of Wheat at 30s. per quarter, and is fully equal to that of the best malting Barley.

The ploughing-in of farmyard manure in autumn for roots has much in its favour if the manure can be had—if not, it is usually applied in the spring, as we have shown. The best results are usually obtained by using a moderate quantity of farmyard manure in the rows, and by drilling chemical manure with the seed. The mixture for Swedes is $\frac{3}{4}$ cwt. muriate of potash, $\frac{1}{2}$ cwt. nitrate of soda, $3\frac{1}{2}$ cwt. steamed bone flour, $1\frac{1}{2}$ cwt. mineral superphosphate. For Mangolds $\frac{3}{4}$ cwt. muriate of potash, $1\frac{1}{4}$ cwt. nitrate of soda, 2 cwt. steamed bone flour, 1 cwt. common salt, and 1 cwt. mineral superphosphate. We can highly recommend these mixtures, but at the same time we say, Do all you can to avoid the heavy expenditure involved in the purchase of them under the most advantageous conditions by folding sheep upon the land so far as is safe and possible.

WORK ON THE HOME FARM.

Store hoggets are being folded on Turnips, the folding being so arranged that the plough can follow closely, and so leave the land ready for spring corn. The higher the sheep are fed the better the manure, but we are satisfied if only we can get sheep enough, even if they only have a little crushed corn and some chaff with the roots. A stickler for high cake feeding expressed his surprise last season at a fine crop of Barley we had after sheep folded on Swedes, the only trough food used being a very moderate quantity of malt culms. No doubt rich manure is a result of high feeding, but undue stress is often placed upon a mere matter of degrees which are practically unimportant.

Ewes are lambing in excellent condition, which we shall do all we can to maintain by a liberal dietary and careful attention. It is impossible to have fine or forward lambs from a weakly or underfed ewe. We like ewes with large substantial frames, well nourished always, and then we may depend upon having good lambs. Mangolds are given freely twice daily, but we are careful to give only as many as can be quite cleared up at each feeding. Every ewe is taken to a separate pen when it lams and is kept there till the shepherd is satisfied that it requires no particular attention and that its progeny is perfectly healthy. It is then turned out with the other sound ewes that have lambed, but all doubtful cases requiring special and frequent attention are kept in a division of the fold immediately under the shepherd's eye. Carbolic oil is as usual of great use in all cases of severe straining and protracted labour. It is indeed a splendid disinfectant, and its timely and judicious use has saved the lives of thousands of ewes that must have been sacrificed without it. As the lambing proceeds every ewe that proves unfit for breeding in any way is marked for withdrawal from the flock with the crones later on. We never retain a faulty animal of any kind for breeding, but invariably prepare it for early disposal in what appears to be the most profitable way. For discarded sheep there is no better plan than to fatten and dispose of them as they become ready for the butcher, which they will be by autumn or early in winter.

METEOROLOGICAL OBSERVATIONS.

REMARKS.

- 19th.—Sharp shower at 9 A.M.; bright sunshine and high wind throughout, but one or two slight showers.
 20th.—Fresh and bright.
 21st.—Bright morning, cloudy at mid-day, wet from 2 P.M.
 22nd.—Bright sunshine and wind all day, rain at night.
 23rd.—Wet from midnight till 10 A.M., sun from 10.30 to noon, gale with showers in afternoon, dull evening.
 24th.—Fine, with occasional sun in morning, solar halo at noon, cloudy afternoon, wet evening.
 25th.—Equally S.W. gales, overcast all day, rain in afternoon.
 Weather still mild, though less warm than in the previous two weeks. After a long period without much wind, we have this week had a succession of gales with occasionally low barometric pressure.—G. J. SYMONS.

A VOICE FROM CALIFORNIA.

MY attention is, for the time being, rivetted upon an article in your issue of December 19th, 1889. In this article Mr. Wright quotes from a gentleman who spent a few months in California, caught a fever there, became homesick, and in the delirium of his fever—for at the time of penning the lines referred to he could not have recovered—he gives vent to the most outrageous statements concerning a country of which, if in his right mind, he is absolutely and totally ignorant. His assertions are so glaringly incorrect that I may well be pardoned for touching upon personal matters in the attempt to show your readers that I know something whereof I speak, and that I have some right to speak plainly.

Regarding references in England, my father, Mr. W. T. Coates of Henley-on-Thames, and Mr. F. Warren of Banbury, late of Croydon, and a friend of the Rev. W. Wilks, the Secretary of your Royal Horticultural Society, can furnish any and all that might be desired. As to my standing in California, I can simply mention the name of Professor E. W. Hilyard, in charge of the Department of Agriculture at the State University at Berkeley, any of the officers or members of the State Horticultural Society, of which I am a Director, the Secretary's office being at 220, Market Street, San Francisco. I have been actively at work in California for fourteen years as a nurseryman and fruit grower, as against the Doctor's sojourn of a few months in, presumably, a very small part of this State, and then ill with fever.

This gentleman observes, and hopes the Journal will be kind enough to insert it, "There is not a blade of grass in the State growing naturally, no hay therefore;" and then this remarkable genius goes on to say, "I have written down a few facts which I have seen myself." Perhaps he will explain how, in a few months, while he was ill with fever, he travelled over a country between 700 and 800 miles long, and several hundred miles wide; and containing 100,218,560 acres! "Not a blade of grass in the State!" While I write, the whole of California, from Siskiyou to San Diego, is an uninterrupted ocean of verdure, except on the high mountains, which at this time of the year are covered with snow. Grass from 4 or 5 inches to 2 feet high, has been so for several months, and will continue the same until May or June. After that time the grasses mature, and there being no more rain, and scarcely any dew until October, the grass is cured, remains sweet, and is more fattening and strengthening to live stock than any artificial feed. "No hay therefore," says this gentleman of amazing insight and keen perception. Because he did not find hay made as in the meadows of old England, abounding in Sweet-scented Vernal Grass, there is "none" here; which reminds me of my little boy, who, when refused any particular food by his mother, assumes the most woe-begone and martyr-like expression, saying, "I haven't anything to eat." The reason we do not cut the wild Grasses for hay is that we can get so much better and more profitable a product by sowing a cereal. The best hay is made of Australian or Sonora Wheat mixed with one-third of Oats, sown any time during the winter months, and cut in May, just when the milk in the kernel begins to thicken. Horses fed with this hay require very little else, unless working very hard. Three tons to the acre is an average yield on valley land. For cattle, or for horses which are not working, Alfalfa hay is often used. Alfalfa (in England "Lucerne") is raised in the whole of Central and Northern California without any

artificial irrigation whatever, producing three crops of hay in one season, and after that serving as green pasturage during the remainder of the summer.

This leads me to another statement of this "disgruntled" (to use an Americanism which is expressive) M.D.—viz., "a country where nothing will grow except under from four to eight hours a day artificial irrigation."

I have no land to sell, neither have I any interest in any which is for sale. I own 90 acres near Napa, besides leased land for my nurseries. I have been growing nursery stock for thirteen years, have raised an orchard of over 6000 trees. I sell from 100,000 to 200,000 fruit trees annually, to say nothing of Grape Vines, berries, ornamental stock, &c., and have never had any occasion to use any water artificially.

In the southern interior portion of the State irrigation is necessarily largely resorted to, for there millions of acres which were thought to be almost worthless, are found to be capable of producing anything that grows anywhere through the introduction of irrigating canals from the melting snows of the Sierras, brought down at great expense for many miles into the broad valleys. The whole of Central and Northern California, extending for hundreds of miles in every direction, is absolutely independent of any irrigation other than that which falls from the clouds. Crops of Indian Corn, vegetables of every kind, Melons, small fruits, orchard fruits—everything, grows to perfection, all that is needed to keep the moisture near the surface being a frequent stirring of the ground with horse cultivators.

In the Napa Valley, where I live, there are ten miles of almost continuous vineyard several miles wide in places, of the leading wine varieties principally. The wines made here are clarets, burgundies, sauternes, and all dry wines and brandies, and farther south ports and sweet wines are more common. The output of the last vintage was about 18,000,000 gallons. At the Paris Exposition California received a large number of awards for her fine wines. The Sonoma Valley, west of Napa, is very similar, but more extensive. Vaca Valley, to the east a few miles, is one unbroken orchard, tens of thousands of acres of the finest varieties of Peaches, Apricots, Pears, Plums, Figs, and every other fruit. Whole trainloads are sent every day for months of fresh fruit to the Eastern States, Chicago being a main distributing centre, but we find a ready market 3000 and 3500 miles away by rail. Thousands of tons are sent to the fruit canneries and preserving houses, the great bulk, however, being often dried or cured as raisins are cured. The Santa Clara Valley, farther south, is a vast region with hundreds of thousands of acres of orchards of French Prunes, Apricots, Pears, &c. The samples of these fruits which I exhibited in London last summer were acknowledged to be far superior to any European product. And all this, and much more, is but a small spot within fifty or sixty miles of San Francisco, and nowhere is irrigation resorted to. I will not take up your valuable space by enlarging upon the raisin districts, where in Fresno alone are 350,000 acres of Muscats all made into raisins that equal, if not surpass, the best Spanish product; of the many miles of Orange and Lemon groves, of orchards of 500 to 2000 acres in extent, of individual vineyards of 10,000 acreage, of Olives, Walnuts, Almonds, Figs, and all the temperate and semi-tropical fruits known.

But what a cruel libel to speak of California as lacking in flowers! As a boy in England I took great pleasure in forming an herbarium of wild flowers, and made a large collection, but in California what a revelation! Here I find scores of carefully cherished annuals and biennials in England growing as weeds by the acre, the woods abounding in Lilies, and the hills with Azaleas and a thousand other choice floral beauties.

The doctor caught fever and ague in the Sacramento Valley; I caught the hay fever in England last summer, making the first two months of my visit far from pleasant. In the river bottoms

there are occasional cases of malaria here, as anywhere else, but why select such a spot, if predisposed to such a complaint, when there are one hundred millions of acres more in California entirely exempt from it? In some parts of the State are great numbers of invalids, a truly one-lunged crowd; but they have come here to prolong their days. California is one great sanatorium for all diseases, for there is here every conceivable climate and temperature, between the shores of the Pacific Ocean and the summit of the Sierras. Such a temperature as 115° in the day and 54° at night is never heard of; the temperature in the Sacramento Valley rarely exceeds 100° , being usually about 85° in the summer, and 60° at night. In the part of the State in which I live it is even more equable, while in San Diego it averages something like 65° all the year.

If I were to land in London on a foggy day in November, and describe the English climate from that experience, it would be no more unjust than this gentleman's description of the Californian climate. Your correspondent does not think any land in California worth five cents an acre. When our orchards and vineyards at five years old and upwards are yielding a net income of 100 to 500 dols. per acre, it will be seen how foolish is this statement. The best valley lands along the line of the railroads sell at about 150 to 200 dols. per acre (£30 to £40), and pay a very large interest on the investment. Equally good lands can be had very much lower, in proportion to the distance from means of transportation to market.

The Doctor found no vegetables fit to eat, and the meat was bad. I will challenge any market in the world to show such an almost infinite variety of the choicest vegetables the earth produces as that of San Francisco or any market towns in California. Asparagus as common and as cheap as Cabbages in England; Cauliflowers and Green Peas all the year round, and indeed almost every known vegetable is to be obtained every month in the year. I will admit that the meat is not all as good as the choice cuts from English beef and mutton, but the reason is, chiefly, that either it is not hung long enough, or the purchaser is green and allows his butcher to impose upon him. As the cookery books say, "If you want choice meat go yourself and select it."

It sometimes happens that in sparsely settled rural districts the best meat is sent to the large markets, as might have been the case with the Doctor. I am able and willing to give facts and figures in support of my statements, which indeed might be made much more glowing without the slightest exaggeration, and could point to hundreds of English and Scotch families here, in affluent circumstances, who can more than bear me out.

If the Editor of the *Journal of Horticulture*, or any representative therefrom, will come and see for himself, I will promise him a royal welcome. To those who may want to inquire carefully into Californian fruit growing I cannot too highly recommend the work just written by Prof. E. J. Wickson, and published by Dewey and Co., 220, Market Street, San Francisco. I could fill pages of the *Journal* descriptive of the beauties and wonders of California and what her incomparable climate and rich soil can produce, all in striking juxtaposition to the acetous, garbled, and pessimistic utterances of your medical correspondent.—LEONARD COATES.

THE USE OF BALLAST, AND HOW TO MAKE IT.

WE have often referred in the *Journal* to the great benefits we have derived from the application of ballast to our stiff soil for all kinds of crops, especially to fruit trees, and our experience with it every year tends greatly to strengthen our convictions—viz., that it is one of the cheapest and best means of rendering a stubborn tenacious soil friable, warm, and fertile. It is a well-known fact that these heavy soils, resting as they generally do on an almost impervious clay, will grow better crops with far less manure than will light sandy soils; moreover, crops are able to endure prolonged droughts better on heavy than on light land. But this proposition is rarely true of heavy soils as found in a state of nature—at least,

as applied to horticulture, for however well they are managed in winter the dashing rains of spring quickly wash the particles of clayey soils into a compact coherent mass, which effectually prevents the free admission of air, sunshine, and rain. Plants under such adverse conditions can never make satisfactory progress. The roots of fruit trees will be strong and fibreless, and their shoots strong, sappy, and fruitless. Of course, for these cold and retentive soils draining must be resorted to as a partial remedial measure, but we have abundantly proved that draining, however well done, can only be considered as an adjunct in the improvement of stiff soils. It is not sufficient to well drain a pot; we must also fill it with a compost that will allow water and air to pass freely through it, and so it must be with the soil of our garden if we wish to grow flowers, fruit, and vegetables to the highest state of perfection.

The mechanical condition of many well drained heavy soils is analogous to putty, and the drought of summer causes them to contract and form deep fissures in all directions, pinching and snapping the roots of plants and rendering them inactive. In wet summers the evils are even greater, for the temperature of the soil can never rise sufficiently high to excite healthy root action, and the invariable result is sappy unhealthy growth, which of itself is sufficient to lay the foundation of disease and ruin in many kinds of fruit trees.

If we inquire why the heavy soils are unkindly we shall find it is largely owing to an insufficient quantity of gritty matter or sand. The earth particles of clay soil are so fine that they run too closely together for the well-being of vegetation. Having arrived at the cause the cure is obvious—viz., add sufficient sand or analogous matter to prevent the cohesion of the clayey particles. This will at once render the soil porous, much warmer, and better suited to healthy plant growth. In the majority of cases it is impossible to get sand in sufficient quantity to be of much use, and the same may be said of lime rubbish, which is very good for the purpose; hence we must make use of the matter to hand of which we have too much. Burnt clay, or ballast as it is called, will be found an excellent substitute for sand; indeed, if properly burnt it is far preferable to sand for rendering stiff land porous. We have had much experience in clay burning the last eight years, having burnt many thousands of tons, and the following is our *modus operandi*.

The cost of burning will be in proportion to the burner's wages and the price of slack in the neighbourhood. One ton of slack, which with us varies from 5s. to 7s. per ton, will burn from 30 to 50 tons of clay, according as it is wet or dry. If plenty of wood can be secured it will burn the clay just as well as coal, and the residue will be still more valuable. An important item in clay burning is a good start. A quantity of tree-bottoms or large logs of wood should be raised to a good heat before much clay be applied, for having secured that the fire may be kept going for an indefinite period. The constant aim of the burner must be to keep the fire at the bottom, and that is where he will require the most coal. To secure this he must go round his fire every morning with a long iron scraper, and draw down the burning clay so as to form a ledge about 18 inches wide at the bottom of the burning heap. On this ledge he should sprinkle his coal rather thickly, and when it begins to burn freely, the clay, with a sprinkling of slack, may be thrown on until the ledge has been carried as high as the man can throw it. In this way we have had fires going continuously for eight months. If the fire is kept in all round it will soon become too bulky for one man to attend to; we therefore allow two sides to go out and carry the heap on lengthways.

More slack will be required in wet weather than in dry, and the burner must see that each layer is burning freely before adding another. Some advise wheeling the clay to the top of the fire, but this we find open to serious objections, as if through excessive wet or other causes any part of the fire goes out it is difficult to start it again; besides, it requires more fuel and labour than by the former method. We have found also that the heat is apt to become too great when the clay is wheeled to the top—the clay fuses, and the result is a hard brick-like substance of no use for mixing with the soil. By throwing it on in layers the burner has the heat completely under his control, and if properly managed a loose gritty mass will be formed that falls to powder with the least touch.

Before use the ballast should be passed through a half-inch mesh screen, and for flower beds sifted through a one-eighth inch sieve. This is important, as its mechanical effects will be in proportion as it is thoroughly mixed with the soil. For damp adhesive fruit borders it is invaluable; the roots become a mass of fibre, and its good effects are apparent in the better ripening and higher flavour of the fruit. We must strive for uniformity between root and branch in fruit culture, for although the trees may carry fruit they will

fail to ripen properly if the roots are in a cold retentive border.—
J. H. W., *Leicester*.

FLOWER CULTURE FOR PROFIT.

TEA ROSES PLANTED OUT.

CONTINUING my remarks from page 83, the handsome and profitable *Maréchal Niel* must have special attention. This variety must annually form long fairly stout shoots, otherwise it is not in a profitable state. It succeeds admirably trained and pruned somewhat on the old extension system practised with Grape Vines. This consists of laying in two main branches right and left along the front plate of roof, these not being stopped till the end of the house at least is reached, this being a pretty good season's growth. From these permanent branches, that are to be the following season a number of lateral growths, should be trained up the roof at short intervals, only the points of these being taken out in the autumn. These strong shoots will early in the following spring push out a bloom at nearly every joint, a single tree being, when at its best, capable of producing two or three thousand blooms. Directly the last of these are over, all these flowering shoots must be cut hard back to near the main branches, and this will result in strong young shoots, pushing out the requisite number of which should be trained over the roof to flower the following season. If preferred a more informal method of training may be adopted, strong leading branches, and some of them will attain a length of 24 feet in one season, being trained over the roof in any direction. These will flower grandly the following season, and in addition also push out strong shoots in places where extra vigorous flowering shoots are cut well back. The latter will bloom freely, and in their turn must be cut back directly they have ceased to flower, in order to obtain the requisite number of flowering growths for the next season. The time will come (I never met with any exceptions) when the early summer pruning will be followed by a second crop of flowers, and this instead of being a matter for congratulation is much to be regretted, as it is a sure sign of weakness and decay. This weakness in the *Maréchal Niel* ought always to be anticipated, other young trees being planted to take their place while yet the original trees are in good health, or otherwise there will be ultimately an unfortunate break in the supply. If they do not canker at the point of union with the stock, or at some of the principal joints in the case of own-root plants, they are yet liable to wear out. As a rule, the stems, whether these be worked or not, fail to keep pace with the very rapid growing branches, and in time a rupture in the sap vessels takes place.

On page 30 the best method of propagating Tea Roses was given, and with these may be included *Noisettes*. If my advice is taken a considerable number of *Maréchal Niel* will be struck every season, flowered once, and then thrown away as being of less value than newly raised plants. Each should be grown with a single growth only; the longer and stouter these become the more profitable they will prove. A well grown young plant in an 8-inch or slightly larger pot can be made to produce blooms in February or thereabouts to the value of 6s., and a good average would be 4s. per plant. The aim should be to get them rooted early, and in their flowering pots in time to spend a few weeks in the open sunshine. When introduced into a moderately warm forcing house in November and December the growths may either be trained up wires on the roof, or say the trellising occupied by Melons or Cucumbers, during the summer, and if this is not convenient then may the plan of lightly training the plants round a few upright stakes be adopted. In the latter case the plants ought to be given good room, and raised well up to the light. A fairly large bud ought to be taken from nearly every joint, and if a little pale in colour they will yet sell readily.

Tea and *Noisette* Roses generally, as I have previously pointed out, will bear moderately hard forcing, but in a more intermediate temperature, ranging from 50° by night to 60° in the daytime, they form much the finest blooms, and remain longer in a vigorous and also floriferous state. All through the winter and early spring months they must be protected as much as possible from cold currents of air, otherwise mildew is liable to be very troublesome. Nor ought they ever to become dry at the roots, the only rest those constantly under glass need being the prevention of flowering during the summer and early autumn months, and abundance of air admitted at the same time. As a rule, the Teas will yield what may be termed three crops before Roses are abundant in the open. To do this, however, they must be well assisted at the roots, especially after they have exhausted the original soil in the borders. They pay well for being treated much the same as Grape Vines at the roots, this taking the form of occasionally partially lifting in the autumn, the front of the border being renewed with fresh compost, and the surface lightly bared to the

principal roots, and top-dressed. The least that can be done is to give frequent liberal supplies of liquid manure, or some kind of special manure may be washed down to the roots. Nor must the foliage of roof-trained plants especially be neglected. These ought to be freely syringed in the afternoon of every clear hot day, otherwise red spider may be the cause of most of the leaves falling prematurely. For a similar reason shading of some kind ought to be afforded during the hottest part of the year. If a decoction of quassia chips and softsoap is mixed with the syringing water, enough being used to make it quite bitter to the taste, green fly will not be very troublesome; but should it gain the upper hand two or three fumigations with tobacco paper is the surest method of getting rid of it. Mildew may sometimes be checked by coating the affected parts with sulphur, but this is not often really effective in other than hot weather. The following will be found an excellent remedy for mildew. Place 1½ lb. of sulphur, 2 ozs of lime, and six quarts of water in a saucepan, and boil down to three quarts. After the solution has settled strain through a muslin bag, store in a jar, and mix with the syringing water at the rate of one wineglassful to four gallons of water.

Many succeed in growing abundance of good Roses, only to mar their work by carelessly consigning them to the markets. It is worse than useless to send fully expanded flowers, and it is also very unwise to send all good and second-rate alike together, as in either case the lowest prices will be returned for the whole lot. The plants ought to be gone over frequently, all buds about half expanded cut and placed in pans of water in a very cool room till the time has arrived for packing. We favour the parcel post for smaller consignments, heavier lots being sent by rail. Prior to packing the buds are sorted over, so many being classed as first, and the rest as second quality, these being duly noted down on the invoice accompanying each box. We use a variety of boxes according to circumstances, but none of them is deep, two layers of blooms being as many as ought to go in one package. The bottom of each is thinly covered with fresh clean moss, and on this the heaviest, and in most instances the best blooms are closely and flatly packed. In comparatively cool weather a strip of moderately stout paper in all that is needed to divide the bottom from the top layer of blooms, but in the summer common Fern fronds or Spinach leaves on the top of each layer serve to keep all cooler and fresher; finish off with more paper, and then sufficient moss or cotton wool to rather more than fill the box. The lid ought always to close down lightly, as should it not do so the rough usage the packages invariably experience must result in great damage to the contents.

Maréchal Niel still realises the best prices, the great demand for these evidently not being on the wane. Very frequently 6s. per dozen (wholesale) can be obtained for the best blooms, not necessarily at the beginning of the season, and that too in small provincial towns, and they rarely fetch less than 4s. per dozen. The second quality blooms range from 3s. 6d. per dozen to 2s., but healthy plants produce but few poor blooms. In this neighbourhood a plant covering the roof of a small span-roofed house annually produces a crop valued at not less than £25, the owner, it must be added, retaining a considerable number of the blooms. The next best in point of value are good blooms of *Lamarque*, *The Bride*, and *Niphetos*, there being always a demand for white Roses. For these we sometimes get as much as 6s. per dozen, but more often than not we have to be content with 3s. 6d. for the best quality, and 2s. for the rest. Catherine Mermet if well grown produces extra fine blooms, and for these 6d. each can be had, but 3s. per dozen is perhaps the average. Yellow Roses are far more popular than those of a pink shade, and sometimes realise slightly better prices; but whatever may be the retail price we seldom get more than 3s. 6d. for either *Isabella Sprunt*, *Madame Falcot*, *Etoile de Lyon*, *Comtesse de Nadaillac*, and other varieties I have previously named. Buds only of *Safrano* and *W. A. Richardson* are of value, but as the former especially is imported in such large quantities the price at first or at the present time is 2s. 6d. per dozen, and later on 1s. 6d.; even at this price we find the former very profitable, a strong roof plant being apparently inexhaustible.—M. H.

PLANT FOOD.

It was remarked in a previous communication that inside borders and pot-grown plants were absolutely under the control of cultivators, and manures could consequently be applied without any disturbing elements interfering with their efficacy. Another remark was made to the effect that much more manure could be advantageously applied in both cases than is generally considered necessary. It may be of interest to amplify these remarks in the present article; and taking borders first, it has to be noted that well fed trees, Vines, Peaches, &c., under otherwise fair treatment,

develope foliage which is less subject to the attacks of insects than is that of underfed trees. Another peculiarity of the foliage is its staying capacity. The absence of insect pests has of course a bearing on this point, but that does not quite explain the fact of the foliage continuing of a deep green until the end of the season without passing a brownish green stage before change of colour and final detachment.

The bearing such foliage has on the next year's crop can only be beneficial, resulting, as it does, in full buds and on a longer continued storage of sap. The amount of feeding required by fruit trees is greater than is, perhaps, generally admitted, for the further reason that the crop they bear is of the most exhausting nature. Flowers are an exhausting crop, but they are a comparatively small affair when considered alongside the production not only of flowers but of fruit and seeds; and if we examine the period when food is of the utmost importance to fruit trees we find it is between the period of the fruit setting and the cessation of growth; and further, that the food required is very much of a mineral nature, or at least a nature which sends us to mineral agents for a supply. During the season of rest, though it is not exactly known what is going on in the plant economy, it is certain some change takes place, and that towards the development of flowers. But one thing we do know, and that is that the quantity of sap taken up by the roots is of the slightest, and that at this stage manures are of no use. We know, further, that the application of manures during the season of rest to plants which have been starved has no effect on the quantity or quality of the flowers which follow in due course. So that we arrive at this point, that the time the tree requires food to forward the fruit begins about the flowering stage, and that simultaneously the food required for the next season's young foliage, early growth, and flowers must also be applied and continued as long as necessary.

The old-fashioned practice of manuring only at the winter season will be seen to have been erroneous in principle, and the result necessarily was that the best managed Vines, except in cases where the soil was naturally fertile, gave up after a few years' regular cropping, and older Vines simply took a rest every second year, unless the crops were kept very small indeed. It is now well understood that potash is a very essential element in all fruit manure, and along with phosphoric acid is the chief ingredient in the ash of all parts of the plant, but particularly of the flowers and seeds. At the same time it is to be remembered that the ash of plants amounts to very seldom more than 3 per cent. of the organic portions, and most often less than that, so that the amount required is really very small. But in practice it is necessary to apply more than the bare amount required to supply these small wants. And the phosphatic element has so important a bearing on the general health of the plant on account of the action which phosphates exert on the formation of roots, that we may apply these in good quantities without giving too much. Then, as potassic manures are only slowly soluble, it is important to let them lie in the soil for a good while before the plants require them. On that account a sprinkling of potassium chloride should be applied to borders during winter, and at the same time a small supply of lime, preferably in the form of lime water, should also be applied, and also about a quarter of a pound to the square yard of superphosphate, or double that quantity of slag phosphate, which is a slower acting agent than the other. If the border has been supplied with 1½ inch of water before the application of these, and a slight sprinkling of soil afterwards with a dressing of cow manure above all, no more water will be required for several weeks, or most likely until root action begins, when another application of water will bring the phosphates into action. Thereafter, a dressing of superphosphate three parts and sulphate of ammonia one part, applied directly after each watering, enough to "pepper" the soil, will do wonders, especially in the case of aged Vines. Rather less may be given to Peaches. Plants stop extracting food in any quantity from the soil when the seed approaches its final stage of development, consequently when the fruit begins to colour feeding may be stopped. Abundance of water is absolutely essential, otherwise mischief will follow.

Dealing now with pot plants, we have to consider that foliage in many cases is all that is required of the plant, and in most others flowers. The plant is often short-lived, and the soil in which it is grown is increased as a rule according to the exigencies of the plant. For such plants no potassic manure is required, but superphosphatic is most important, and should always be employed as a surface dressing. Its action is greatly stimulated by an occasional dressing of a nitrate. But it is one of the greatest fallacies in plant culture to depend on a nitrogenous agent solely, as growers of Chrysanthemums have been doing. More than is absolutely necessary of either lime, potash, or phosphates has no evil effect on plants. What they do not use does no harm; but an excess of the nitrogenous agent is injurious. Manures should be applied after

watering, and the superphosphate should be sprinkled evenly over the surface of the soil, so that the roots may find it the more easily. They should be applied regularly from the beginning of the young plant's existence, leaving off at times of repotting until fresh roots are formed. They have a good effect in colouring Crotons and other plants, and in giving quality and colour to flowers—B.

(To be continued.)

CARNATION SOUVENIR DE LA MALMAISON.

CARNATIONS have become exceedingly popular during the past two seasons, and they have now to be grown in quantity where previously a few specimens were equal to the demand. No doubt they will also find their way into most gardens where choice flowers are appreciated, but where at present their owners are as yet unacquainted with these, the aristocrats of the Carnation family. I well remember the first time I saw a plant of the *Souvenir de la Malmaison*. It must be a quarter of a century ago, when making a little tour among gardens in early summer, I found in one of those visited a large plant trained to a balloon-shaped trellis with shoots and flowers tied down in the old-fashioned style. That plant is the one thing I remember distinctly of all the others in the conservatory, and ever since I have had a liking for *Malmaisons* above most other flowers. My cultural experience has been much the same as that of most people—some failures, until the right track has been struck, and thereafter the road has been comparatively smooth and easy. I shall here indicate some of the points which render *Malmaison* culture uncertain. The initial one to beginners is that of securing a strong healthy stock to start with. I have had plants through my hands on several occasions which no amount of attention could induce to live. Close-jointed growth with foliage to the soil and plenty of roots in the latter is needed to make a start with.

A pest which inexperienced growers often allow to work irremediable mischief before noticing anything wrong is found in a wingless aphid. This insect feeds, out of sight at first, on the young foliage, and if allowed to go on without check it simply necessitates either the cutting back of all the growth infested, so destroying the season's bloom, or it may even destroy plants otherwise not in the best of health. The only certain method of escape is to dust the young growing points with tobacco powder, repeating the application at regular intervals. Many plants are destroyed by a rust or fungoid growth which attacks the foliage. Whenever a collection is attacked the greatest watchfulness is necessary and every bit of affected leaf must be destroyed. This is a very common means of failure with *Malmaisons*. I should be very glad to hear of some simple and efficient method of clearing unhealthy stock of this virulent parasite.

As the last point to be noted in order to keep a healthy stock, I think it is a mistaken policy to grow other than young plants. If large plants are wanted they ought to be grown on without allowing them to flower until they have reached the size desired; and, though these should be three or four years of age, all the growth will be short with broad healthy foliage, and to all intents as young and strong as one-year-old plants. Those allowed to flower as they like become tall, the bare old stems unhealthy and unfitted to continue producing good blooms, and not uncommonly die right back. Aphid, rust, and old plants are, I think, most inimical to success, but in common with other Carnations they do not like a close warm atmosphere. Far better grow them in a cold frame than stifle them as is too often the case.

In direct cultural details there is nothing difficult to master. Propagation is effected either by means of cuttings or layers. The most common time to increase by the former method is in autumn, keeping the cuttings in a cool house through the winter, and potting in spring when well rooted. They also strike freely during summer if dibbled into a light soil in a perfectly shaded position, and protected with a bellglass until rooted. Layering may be effected at any season, but from February until the end of August the rooting process is much more rapid than at other times. Roots are formed in from ten days to a fortnight under the most favourable conditions, and as soon as a few roots are made the junction between the old plant and the layer should be severed. The shoots may either be layered into thumb pots, or into a thin bed of light open soil. In the latter case there is less risk of the young plants suffering from any neglect; though, with due attention, the pot layers are ready first. If growers have a sufficient stock to keep a few good plants to bloom throughout winter, these will be in good condition to layer now (the beginning of February). The way we do these is to sink the pots in the border of a late Peach house, then spread a layer, 2 inches thick, of leaf soil and sand on the surface of the border, laying the young growths therein. If always kept moist

roots are quickly formed, and by the beginning of March the rooted plants are ready for placing into 3-inch pots. Late layers made in the same way in October will be well rooted at the same time, or perhaps a few weeks earlier. These may either be grown without stopping, when they will flower in late autumn or winter, or the points may be taken out and three to six of the strongest growths left, which will furnish plants for flowering in early spring. Pots 7 to 8 inches diameter will be required for these.—N. B.

(To be continued.)

EMIGRATION OF GARDENERS.

(Continued from page 83.)

SIGHT-SEEING, like everything else, comes to an end, and so our friend went to work, carrying cotton bales seven days at 1½ dol. per day with the "darkies." Hard work on a sugar plantation, in the boiling houses, at 1 dol. 75 cents. per day for five weeks proved its unsuitability for the white man; consequently he sailed up the Mississippi to Memphis, walked forty miles along the bank, getting work on "levy"—i.e., raising the banks of the Mississippi, to prevent inundations, at 2½ dols. per day without board. At the end of eight weeks he was seized with ague or malarial fever, and went into a hospital at St. Louis, paying 12 dols. per week for board and medical attendance. After eight weeks he was ordered north, therefore made for Chicago, and thence to New York. It is needless to say that the western fever and the malarial visitation made speedy end of the 500 dols. intended for a trip home. A precarious existence had to be maintained by picking up work in Long Island and New Jersey, finally drifting to Philadelphia, having to enter a hospital, receiving every medical attendance and the kindest care from sisters of mercy for months in-and-out; in the intervals working at odd jobs, chiefly among farmers, and only getting enough to make ends meet. This brings us to the end of August, 1889, when medical men advised a change to native air; no remedy so effectual, except Sir Walter Raleigh's headsmen's axe—"sharp medicine, a cure for all diseases." Baltimore was reached with scanty means, and in proof that no man can know too much, the experience of the sea, even oyster dredging, secured a passage home in the steamship "Baltimore," bound to Glasgow with a general cargo, including 743 head of cattle, the farming experience securing in addition to the working passage 10 dols. wherewith to land on native soil. After a very rough passage of fifteen days he landed at Glasgow, with clothes all spoiled and 10 dols. of the United States of America money to get a "rig out." The idea was to get work of any kind to subsist, and throw off the malarial effects of the Mississippi swamps, then to see the old folks at home, and return to America. This, good as it might be in inception, was not so easy of execution. In fact it failed, and we are glad, as it tends to confirm our conviction that the horticultural horse has been ridden too fast and too long in this country to last. Our friend tried Glasgow, the gardens of Edinburgh, and trudged along by way of Berwick, Newcastle, York, Peterborough, &c., to London, trying for work all along the route, and only had four days harvesting with a farmer near Hexham, and one day machine threshing near Ware, in each case at 2s. 6d. per day and drinking, which our friend declares to be the worst practice under the sun, the master taking advantage of the weakness of the men to get more work done than is paid for in cash.

Work was tried for all round London, then Birmingham, Dudley, Wolverhampton, Leeds, and Sheffield. A return was made to London. The missive came, "I should like to see you before I return to America, for I am heartily sick of England, convinced from what I have seen that the unemployed gardener and agricultural labourer can do better in America than here; the field is larger, and the opportunities greater. I think I am cured of the ague, and making Liverpool shall work my passage out and smuggle myself in, as pauper labour is not allowed to land by the United States Government; but that will hardly be necessary, as I have many friends there who will be pleased to welcome me back again." There is little more to tell, only of matters horticultural, which are reserved for another paper, something may be said. Suffice it to state that our friend sailed from Liverpool January 4th, 1890, in the Guion Line mail steamer "Wyoming" as a passenger.—UTILITARIAN.

TECOMA JASMINOIDES.

GREENHOUSE climbing plants are always in demand, and it is sometimes a source of difficulty to secure sufficient diversity in roof-covering occupants of this character. Few novelties are added to those suitable for the purpose, and we have to hark back amongst those introduced during the present century to find sufficient to make up a

good list. In some gardens the Tecomas, with their near relatives the Bignonias, are known and valued, but this is by no means generally the case—yet easily grown plants like these should not be neglected. *Tecoma jasminoides* is particularly worthy of a place, yet when it is exhibited, either in the metropolis or the provinces, it is comparatively new to the majority of the visitors who admire its elegant flowers and delicate colour. The flowers are produced freely, and vary from white with a rosy centre to a uniform pink hue, differing in the brightness of tint, and some of the best marked of these variations have received distinctive names.

The plant succeeds in a compost of turfy loam, peat, and sand, or

FIG. 13.—TECOMA JASMINOIDES.

good leaf soil can be substituted for the peat if more convenient. Planted out it grows freely, but it also succeeds in a pot, needing thorough drainage in any case.

CULTURE OF THE MUSCAT GRAPE.

(Continued from page 92.)

MUSCAT Grapes generally require careful cultivation and good light houses, so that they can obtain a large amount of heat from a natural source, as well as being supplied with sufficient means to obtain the same artificially. Lean-to houses with a south aspect I consider best, although good Muscats are grown in different style of houses and aspect. Muscat Hamburg, Madresfield Court, and the Frontignans might be grown well together. They will succeed with rather less heat than the Muscat of Alexandria.

In the arrangement of the hot-water pipes in vineries I strongly advocate the equal distribution of the pipes through the house. It was formerly the system to place them altogether along the front of the houses, and I have invariably observed that the bunches of Grapes

nearest the hot-water pipes set the best, so that if the pipes are distributed through the house a greater chance of obtaining a good set is the result. The soil I have found Grapes to succeed in best, and especially Muscats, is a good strong yellow loam, not the turf only, but dug 6 to 8 inches deep, according to the quality. The turf alone I consider not so good, as it is not so substantial, and does not produce such a substantial growth. Cultivators have not always the chance of obtaining the soil they would like, but have to use that nearest at hand. I have known instances where soil has been carted from a distance when that more suitable was close at hand. I like to have the borders composed of solid material, so that they will retain the food for the Vines if the borders are light and fibry. Much of the food supplied to the Vines passes away too quickly. A good proportion of brick and mortar rubbish is necessary to keep the soil open, and a good sprinkling of half-inch bones is a great advantage, as they act mechanically as well as producing food for the Vines.

In making the border I like to have the soil firm, having it rammed with wooden rammers. About 2 feet 6 inches depth of soil is ample, with about 6 inches of drainage. The border is about the width of the house if possible. Vines may succeed for some time in very narrow borders, but narrow borders are like small pots for large plants, and very liable to mismanagement. With regard to inside or outside borders, in a general way outside borders are preferred provided means can be had for keeping off the cold rains and snow. They are not so liable to be mismanaged, and do not require nearly so much labour as inside borders, for if they are well managed it is rare that they will require watering. The labour required to supply the wants of inside borders is very great, especially where the water is not conveniently situated. For early forcing inside borders are probably best, although I have seen excellent Grapes produced from Vines (chiefly Black Hamburgs and Frontignans) grown in outside borders, where the fruit was ripe the first week in April.

Outside borders I keep well mulched with good manure the greater portion of the year. After the Grapes are ripe the mulching is gradually removed, and the borders exposed to the weather until the approach of frost. If good manure is not to be had, or is objected to, I recommend a dressing (sufficient to colour the ground) of about equal portions of superphosphate of lime and guano, and in the case of old borders which have been annually mulched with manure a good dressing of quicklime would prove beneficial. As I do not consider it advisable to water outside borders, except under special circumstances, it is necessary that assistance be supplied the roots in the mulching and top-dressings to be washed in by the rain. In preparing a new border it is best to make it about a fourth part annually until the desired width is attained, but by no means should the roots be cramped for want of room in the early part of their existence.

Planting may be done in the spring or early autumn, the former preferred for inside borders, and the latter time for outside, as the soil would be much warmer then than in spring, so that the roots would get started into the new soil previous to cold weather coming on, and the Vines would be enabled to start strongly in the spring through having a few established roots to commence with. When the Vines commence growing, give them every encouragement to make a strong substantial growth, with sufficient heat and air to enable the wood to become solid as it is made. The leader is stopped once or twice, and the laterals frequently, so as to concentrate the vigour in that part of the rod which will be left after pruning. If the Vines have made satisfactory progress the first season we leave from 4 to 6 feet of rod after pruning.

Cropping I consider requires as much forethought and consideration as any matter connected with the cultivation of the Vine; so many err on this point, while all other matters connected with successful cultivation are scrupulously carried out. It is known that Vines, when well cultivated, produce more fruit than they can properly mature to give general satisfaction, and it goes much against the will of many cultivators to remove many fine bunches at thinning time, and to this matter I must plead guilty, but experience is better bought than taught, as it is more effectual. Young Vines should be cropped lightly until they become established. A great many are too anxious to procure a full crop before the Vines are capable of producing it, but it is not at all times the fault of the cultivator, for some owners of Vines are not very well pleased unless they can see what they call good crops, and dearly are they sometimes paid for. After much attention and close observation on the matter of cropping of Vines, I consider about a pound weight of Grapes to the square yard of roof covered taken from established Vines is a fair crop, and the cultivator when he is acquainted with the Vines can at the thinning time fairly estimate the number of bunches to leave,

although sometimes with vigorous Vines they may exceed one's expectations; but should they become over-weighted with fruit they will surely fail to properly mature them, however highly they may be fed, and bad finish with shanked berries will be the probable result.

SUMMER TREATMENT.—When the Vines are growing they should be encouraged, as previously stated, to make a substantial growth by admitting air upon all favourable occasions, and allowing plenty of light among the foliage by keeping the laterals thin, but we must be guided by the nature of the house the Vines are growing in. In houses which are constructed to admit the largest amount of light more growth may be allowed, but by no means should they become thickly crowded, especially in the case of Muscat of Alexandria, which requires abundance of light throughout its growing season, both for the fruit and wood, and if this is provided from the time of the berries setting, other things being satisfactory, they will not fail to finish well. I am no advocate for allowing a dense mass of foliage, recommended by some to encourage root action. All available space should be filled with foliage sufficiently thin to admit the sun between the leaves. The shoots are stopped the second leaf beyond the bunch, and rub out all laterals along the shoots as they appear, except one between the base of the shoot and the bunch to act as a kind of safety valve to prevent the base buds bursting. This and all subsequent laterals are closely stopped or rubbed out if there is any fear of too many leaves forming. This treatment induces the base buds to become better developed than they otherwise would do, and the foliage being no way crowded they are well matured, and invariably produce a good bunch the following season. A sharp look out is kept for the usual insects the Vines are subject to, for if they once obtain a footing they cause much trouble to prevent their injuring the foliage. A sprinkling of liquid manure about the house in the evening is effectual in keeping red spider in check, or a little placed into the evaporating troughs will also cause the foliage to assume a dark green colour, so much desired. I pay strict attention to the ventilation, not losing an opportunity of admitting air both at the top and the front of the house when favourable, and especially to avoid the houses becoming excessively hot before air is admitted.

Watering requires careful attention if the borders are entirely inside, and the cultivator must be guided by circumstances, but as much harm is done by giving too much water as too little. Vines growing in narrow shallow borders will of course require more frequent applications than those not so confined. The borders, if they are inside, are thoroughly soaked previously to starting the Vines, and in doing so use liquid manure tolerably strong, so as to furnish the soil with plenty of food for the roots to feed upon. With Vines started in February we usually find about six good waterings sufficient to bring the crop to maturity, given at intervals according to the state of the weather, using liquid manure alternately, but not so strong as it is applied in the winter time. The borders are well mulched with good fresh cow manure containing a fair proportion of straw. I also give the borders a sprinkling of lime once during the year. The manure is kept moist during the growing season by daily sprinkling with syringe. After the crop is cut the borders are well soaked with clear water, then a good watering of liquid manure follows. Outside borders, if kept well mulched with good manure during the growing season, are rarely watered. Muscat of Alexandria and Mrs. Pince's Muscat require a good temperature to grow in. We commence with a temperature of about 50° at night, 55° by day by artificial heat, with an additional 10° from sun heat, and gradually rising from 70° to 75° at night, and 80° to 85° by day from sun heat. I have never failed to obtain a good set when the above temperatures could be secured, and a good shaking of the Vines when in bloom to distribute the pollen.

The Frontignans, Madresfield Court, Muscat Hamburg, and Châsselas Musqué do not require so high a temperature. The latter variety and Madresfield Court are apt to crack their berries unless carefully looked after as regards ventilation, but if freely ventilated and carefully exposed to the sun the risk of their cracking will be materially reduced. During the growing season, after the fruit is set as well as before, the Vines receive an occasional syringing to cleanse the foliage, which also assists in keeping away red spider, but I am careful that very clear water only is used. Water containing lime would not be suitable owing to its leaving a sediment upon the berries. Syringing the foliage should be performed carefully and early enough in the afternoon to allow the berries to dry quickly, otherwise they would be discoloured if the water remained upon them long, and the skin of the berries should become firm before using the syringe for the foliage; no evil then results from the practice. As the fruit approaches maturity syringing the foliage is discontinued.

Pruning.—After the foliage begins to assume the colour indicating maturity we commence shortening the laterals slightly, and as soon as the foliage is off finally prune, and in doing so invariably cut back to one bud from the base, as bunches sufficiently large for ordinary purposes can be procured from them. Vines in good condition will often produce bunches from 3 to 4 lbs. weight from the base buds, and invariably of a better shape than those from buds farther along the lateral.

After pruning the rods are well scrubbed, using a new brush and soapy water, removing previously any loose bark that may be hanging about merely for appearance sake, but by no means have the old bark removed unless it is beginning to leave the rods; the house then receives its annual cleaning as soon as convenient, and is ready when the time comes for another start.—W. SIMPSON.—(Read at a meeting of the *Liverpool Horticultural Association*.)

RELABELLING.

WHERE the houses devoted to orchids have been cleaned, as well as the plants, there will be time for preparing new labels. Those made of wood are almost useless for these plants, and require renewing every season. This entails more labour than can be spared in many establishments. The best method is to have stout galvanised wire supports, the wire being turned downwards at the top for about 1 inch and then upwards. On the end of the upright piece a zinc label with a hole through it, a little larger than the wire, is placed, and this rests at the bend where the wire is turned upwards. If closed after it is placed on with a hammer the label cannot come off. The label should be written before it is placed on the wire, and special notes can be made on the back. A solution of platinum must be employed in ink, which can be obtained from any chemist, and though rather dear a small quantity will suffice for a large number of labels. When obtained from a reliable source it will often fail to write on zinc, passing over it as if the label had been greasy. This is due to the solution being too strong, and if it is reduced by adding water the labels can be written clearly and without much trouble. A piece of hard wood finely pointed is better for writing on these labels with than a pen. Once those to whom the writing is entrusted are accustomed to use it. We never think of using a pen, which the solution quickly destroys.

BASKETS AND PANS.

It is a mistake to leave the preparation of these until plants are ready for being placed in them. The work of shifting the plants takes fully double the time that would be the case if the baskets and pans for suspending from the roof were supplied with wires ready for use. Copper wire is the best for this purpose, of a stoutness that will not bend and dangle about when the basket or pan is lifted down for watering. A hook at the top is better to hang them up by than a loop, but the latter can be made more easily than the former. The most important matter to be taken into consideration is to suspend them in such a manner that they can be taken down quickly, and as many as possible, without the use of steps. Plants that are suspended out of reach are very liable to be neglected, and suffer in consequence, either from too much or too little water, and not unfrequently from insects, before it is discovered that they have been attacked.

Suspend all plants as far as possible where the aid of steps can be dispensed with. Where quantities have to be overlooked daily and steps are a necessity, the amount of labour in watering is increased materially. This should be kept in mind when baskets and pans are being wired ready for use.

BLOCKS.

These are suitable for many Orchids, and when properly treated they do well upon them. We have found that the small thin pieces of wood so generally used dry too quickly for the well-being of the plants. These should be avoided as much as possible, for when the plants are once established upon them it is difficult to take them off and place them on larger ones. The only practicable course is to secure the one to the other. The size and growth of plants must be taken fully into consideration when placing them on blocks; for instance, some of the *Oncidiums*, unless they are large pieces, will do on small blocks for many years, in fact, until the wood is sufficiently decayed to be picked and washed from the

roots. A number of blocks of various sizes should be prepared ready for use. Almost any wood will do, but we prefer that of a moderately hard nature, so that they will last as long as possible. Branches of various sizes are selected for this purpose, and if they will allow of it are split in two; if not, they are made flat on one side, as a flat surface is more convenient on which to secure the plants than a round one. Sharp angles are also removed. The bark should be removed, because it quickly commences to decay and part from the wood, and soon proves a splendid harbour for woodlice and other pests, if there are any about, and have the least chance of getting to the plants. After the blocks are prepared they should be thoroughly charred, which adds to their preservation, and probably assists the plant in its growth by absorbing the ammonia from the atmosphere.—ORCHID GROWER.

ORCHIDS IN FLOWER.

THE following Orchids are flowering in Messrs. John Laing and Sons' nurseries at Forest Hill, S.E.:—*Cœlogynis cristata*, Chatsworth var., and *alba* (*Lololeuca*); *Calanthes vestita* and *rubra*; *Cattleya chocoensis*, *Percivaliana*, and *Trianae delicata*; *Cypripedium callosum*, *Harrisianum*, and *insigne sylhetense*; *Dendrobium crassinode Barberianum*, *fimbriatum*, *Jamesianum*, *nobile*, *pendula*, *Pierardi*, *Wardianum*, and *splendens*; *Lælia harpophylla*, *Lycaste Skinneri*, and *superba*; *Masdevallia Harryana*, *igneae*, *Lindeni*, *polysticta*, *tovarensis*; *Odontoglossum Alexandrae*, *asperum*, *Cervantesi*, *Oerstedii*, *pulchellum majus*, and *Rossi majus*; *Oncidium barbatum*, *cucullatum*, *Forbesii*, *ornithorhynchum*, *reflexum*, *splendidum*, and *varicosum*; *Phaius grandifolius*, *Pilumna fragrans*, *Polystachya pubescens*, and *Zygopetalum Mackayi*.

ORCHIDS AT HEATHFIELD HOUSE.

THE readers of the *Journal of Horticulture* will be glad to know that the extensive range of glass houses at Heathfield House, Low Fell, Gateshead, late under the management of Mr. A. Methven, and now under Mr. J. Wood, late foreman in the gardens of Sir Chas. Tennant, The Glen, Peeblesshire, have not lost their prestige or interest in the horticultural world. Just now a plant is flowering of *Odontoglossum grande* with three stems in a 6-inch pot, two with six flowers each, and one with four, the flowers averaging 6 inches across. This plant at the time of my visit was flowering in the cool *Odontoglossum* house. The enclosed photograph will give some idea of the plant and the imposing appearance it had. *Odontoglossum cirrhosum* is bearing a fine seed pod.—S. S.

[The photograph sent represents a well flowered plant of *Odontoglossum grande*.]

APRICOTS.

I NOTICE a correspondent, "C. H.," asks those who have been successful in Apricot culture to give the method they adopt to secure a crop, or in words to that effect, and this in the midland counties. I will try to show "C. H." the way I made the culture of Apricots a success in what may safely be termed one of the worst localities to grow them, or, in fact, any hardy fruit. The garden was in a veritable bog, with a lake each side and a couple of streams of water passing through the grounds.

Although Apricots had been grown fairly well in this garden many years ago, there was not a tree worthy of the name when I took charge, in the summer of 1878. Yet Apricots were much wanted, and had to be bought. I have many times paid cottagers 4s. and 6s. per dozen for fruit. But the purchase of fruit was not in accordance with economy, which was most rigidly practised during my eleven years' stay in this garden. Therefore I asked permission to try my hand. The reply was, "I should much like you to 'try,' but I do not think you will succeed." However I did try, and succeeded too.

The first thing done was to select a good wall facing south-east long enough to hold a dozen full grown trees. A few old Pear trees were removed, the soil taken out and spread over the border, which had become too light in consequence of over-dressing with manure. This was prepared for the reception of the Apricots in the following manner. The soil was removed to the depth of 3 feet, and 4 feet wide; the bottom was covered with 6 inches of chalk, well rammed and trodden down, then ordinary agricultural drain pipes were placed very carefully over the chalk with a good fall towards a main drain in the garden walk. At 4 feet apart, between the pipes, was put as much brick rubbish as was thought necessary to carry off the water. A good layer of fresh cut loam, grass side downwards, was next supplied. Then we mixed a quantity of loam that had been stacked for six months with equal portions of charred refuse and bricklayers' refuse. In this the trees were duly planted and nailed to the wall, the roots being covered with long stable litter. There was no pruning, but

the shoots were laid in their full length. The only protection used to ward off spring frost was a few laurel boughs, just at the most critical period when the flowers expanded.

The result is that these Apricots are well worth looking at, and last year the crop was splendid. As soon as it was seen that these showed signs of "doing well" I was allowed to proceed to renovate and replant the Plums against the walls. Peaches and Pears, and even the Vines, were all lifted and replanted with similar results. I have permission to visit this place though I have been some months away from it, and if the editor will accept them I will give the readers of the Journal a few notes about the place in general.—A PRACTICAL MAN.

[We shall be glad to have the notes referred to by our correspondent.]

BOUVARDIAS.

FEW flowers are more pleasing than the best Bouvardias, and few more easy to grow, a happy condition which is found to accompany both the beautiful and the useful in the case of so many flowers. Some plants we may have too many of and their flowers be lost, but the Bouvardia is not one of these, for either in pots or for various purposes when cut it is never unwellcome or despised. Bouvardias are of easy increase, which is effected either by cuttings made of the tips of growing shoots in spring or by pieces of the root cut up and started into growth. The latter is, I think, the method by which the best results are obtained. The roots can be taken any time from February till April, strong roots yielding the stronger growths. These need not be cut up into over-small pieces, as a root which starts two or three buds naturally makes a much better plant than those which start one growth only. The simplest mode of culture, and the best one, moreover, never allows the plants to be potted until they are wanted for flowering. For starting the roots ordinary cutting boxes are prepared by half filling them with light open material, nothing being better for the purpose than light flaky leaf soil. On this the roots are spread thinly and merely covered with the same material, the whole being finished with a layer of moss, which is effective in keeping the soil in an equably moist condition with a minimum amount of watering. A little bottom heat is of service in starting growth, and this is secured by placing the boxes either on or over the pipes in a vinery or other forcing house. When growth is well started the moss is removed and the plants have a better growing position. If placed in early in spring the plants will require shifting into other boxes, but if late they may be left until ready to plant out. Essential at this period are plenty of light, a good temperature, and an unremitting attention to pinching. If these points are attended to the plants will make rapid growth, which will be thickened by the continued pinching, and dormant buds will throw up from the root and further add to the size and strength of the plants.

By the middle or end of May they can be transplanted without danger into cold frames, which for some time will be better kept close and slightly shaded, but as summer progresses the sashes will be much better dispensed with. Pinching must be continued, and it will be found a good practice to remove altogether all growths which are weakly, as these are really not of the slightest use either to the plant or to the cultivator, a less number of strong growths being of much greater value than any number of weak ones. If wanted to bloom early pinching must not be continued too late, indeed the beginning of September should see this discontinued for all the stock. At this time, too, it is necessary to partially raise the plant, choosing dull weather to do so, and if a few hot days follow, rather shade closely than water the soil, as the plants will be more benefited in one way than another, the wood made firmer, the young roots less watery, and the flower buds more regularly set.

By the third week of September the plants must be transferred to pots, the size needful to employ much depending on the nature of the compost in which the plants had passed the summer. If good plain loam smaller pots would do than were a light open compost used. Any way, the pots should not be so large as to have the roots away from their sides, a pot packed full of roots in a few weeks being the object to aim at, and the fresh soil over the drainage and on the surface will be sufficient to carry the plants through their flowering season with the aid of a few dressings of manure. When potted place them in a sheltered corner out of doors until the second week of October, then get them into an airy pit where they can be kept growing, and where they will develop flowers rapidly. An average temperature of 50° to 55° suits them well until December is reached, when if it is intended to keep the same plants flowering they must have a stove heat in order to induce fresh breaks and to bring forward the trusses.

However, it is perhaps the better plan to dry the plants about the new year, keeping them cool, though not cold and dry.

The second year the growths must be cut well back in the same way as Fuchsias and allowed to start in much the same way. They may also require to be shaken out and repotted, and will make good plants either placed out in the same way as advised above, or the pots may be plunged and water supplied freely, when the plants will come in useful early in the season, and continue in bloom for a very long period. Bouvardias, it must be understood, have no antipathy to the knife of the flower gatherer, but the more trusses there are cut the more they are prepared to contribute, until the dimmed light of the winter season puts a stop to this characteristic. We grow only a very few sorts and may cultivate still fewer in the future. The best singles appear to be Hogarthi and Vreelandi, respectively red and white, but of far greater value is the now old double white sort Alfred Neuner. Strong growths alone allowed to remain and perfect bloom places the trusses of this much in advance of others, and if extra fine examples are particularly wanted a little trimming out of the pips when in bud will yield good results. Green fly should be kept off the plants, as they prove fatal to the undeveloped trusses, rendering these quite worthless if allowed to gain a footing.—A SCOTCH GARDENER.

EVENTS OF THE WEEK.—The Royal Society meets to-day (Thursday) at 4.30 P.M. The Royal Botanic Society has a meeting on Saturday at 3.45 P.M., and the Royal Geographical Society at 8.30 P.M. on Monday. The chief horticultural event of the week will, however, be the Royal Horticultural Society's gathering on Tuesday, February 11th, when the Fruit, Floral, and Orchid Committees will assemble at 12 P.M., and the annual general meeting of Fellows will take place at 3 P.M.

— THE WEATHER IN THE METROPOLITAN DISTRICT has again been extremely variable during the past week. It has, however, been generally mild for the time of year, with slight frosts on two or three mornings; rather dense fogs have prevailed in the earlier part of several days, followed by clear bright weather.

— GARDENERS' ORPHAN FUND.—At the monthly meeting of the Committee, held on Friday night last, Mr. G. Deal in the chair, the following special receipts were announced:—From a concert at Worksop, £56 4s. From Chrysanthemum Shows at Reigate, £50; Edinburgh, £5; and Market Harborough, £1 1s. From money boxes—Mr. Cannell, Swanley, £1; Mr. Herbst, Richmond, £1 2s.; Mr. Vallance, Bristol, £1 11s. 6d.; Mr. Hughes, Birmingham, £5 8s.; Mr. Dodds, Herringswell, Mildenhall, Suffolk, 5s. 8d.; Mr. Tubb, Minley Gardens, Farnboro', £1 5s. 1d.; total, £10 12s. 3d.; making an aggregate amount during the month of £122 7s. 3d. A vote of condolence on the death of Mr. Wildsmith, who was a good supporter of the Fund, was directed to be entered on the minutes and sent to Mrs. Wildsmith.

— WILL some of your correspondents kindly tell me what is best to plant on the BACK WALL OF A LEAN-TO VINERY? The wall is about 16 feet high. I have Camellias planted there, but the flowers flag and will not stand when cut. I am afraid the heat is too much, for I start the house on the 1st of January. I should like to grow Tomatoes, but I am afraid the Vines would shade them too much.—M. G. D.

— IMPROVED BLACKBERRIES.—Your correspondent "Rubus," page 61, has spoken very favourably of the Parsley-leaved Bramble, and I, for one, can endorse all that he has said in its favour. It is a vigorous grower, a prolific bearer of large fruit, which have a brisk flavour. When we purchased our stock of Rubus laciniatus, at the same time we purchased an equal quantity of the American variety called Wilson Junior. The latter has died out, seeming to have a weak and puny habit, and not at all suited for our part of the country, although Blackberries of the common English varieties are plentiful and very fine hereabouts; and as an instance of how vigorously they grow, one of our men in digging round the edge of a Rhododendron bed near a spring in the pleasure grounds, called my attention to a shoot a Bramble

had made during 1889; it was 3 feet long, and as thick as a man's thumb at the lower end.—R. MAHER, *Yattendon Court Gardens, Newbury.*

— GARDENING APPOINTMENTS.—Mr. H. Dunkin, for some years foreman at Longford Castle Gardens, has been appointed gardener to J. Harris Sanders, Esq., Porters Park, Barnet; and Mr. T. Vagg has been engaged as gardener to J. Theobald, Esq., M.P., The Bedfords, Havering-atte-Bower, Essex.

— USEFUL PLANTS.—The "Kew Bulletin" for February is devoted to letters and articles upon "The Manufacture of Quinine in India," "Maqui Berries for Colouring Wine," the berries named being the produce of *Aristotelia Maqui*. The other subjects dealt with are "Vine Culture in Texas," "Phylloxera in Victoria," "Botanical Exploration in Cuba," and "The Sugar Production of the World."

— A CORRECTION.—The difference between the statement in the couplet quoted by Mr. Arnott as to the flowering of Snowdrops and the actual time when they flower is not to be accounted for by my suggestion of the difference between the falling of Candlemas Day under the old and new style, the effect of which is exactly the reverse of what I stated (as I have since remembered), and only makes the difference the more glaring. How I made the blunder I do not know, except that *humanum est errare*, and that I wanted to find a reason for the old lines.—FRANCIS STERRY.

— THE SPHINCTER GRIP ARMoured HOSE COMPANY.—We are desired to mention that the following awards have been made to the armoured hose of this Company:—A bronze medal (the highest award for hose exhibit) at the Brighton and Hove International Exhibition; also the first prize and medal at the Paris Exhibition, 1889; first prize (silver medal) at the Birmingham Electrical and Industrial Exhibition, 1889; certificate of merit and special mention at the American Exhibition, London, 1887. The Company have added five new patented improvements to their machinery since they first placed this hose on the market. The hose is now in extensive use in private gardens, government and public establishments in this country and the colonies.

— THE HAYWARDS HEATH HORTICULTURAL SOCIETY.—Judging by the attendance of members at the first annual meeting, and the interest that was manifested in the proceedings, this young Society bids fair to have a stimulating effect on horticulture as practised by gardeners and amateurs in Mid-Sussex. The balance sheet showed that the receipts during the past year amounted to £196, and as the expenditure was £155 10s., the substantial sum of £41 2s. remained in favour of the Society. This is a very good beginning, and a favourable augury of future prosperity. Mr. S. Cooper is the President, and Mr. A. Willmot the Honorary Secretary of the Society.

— THE RAINFALL AT CUCKFIELD, MID-SUSSEX, for January was 2.33 inches, being 0.40 inch over the average. The heaviest fall was 0.45 inch on the 28th, rain falling on twenty-five days. Highest temperature, 54° on the 7th; lowest, 27° on 1st and 13th. Mean day temperature, 47.2°; mean night ditto, 36.1°. Mean temperature, 41.6°, 3° above the average. Remarkable mild month, thermometer only falling on four occasions below freezing point.—R. INGLIS.

— I SEND the following particulars of WEATHER OBSERVATIONS taken through last month, thinking they would be of some service for the Journal. Rain fell upon nineteen days; the largest amount fell in one day, being 0.33 inch; the smallest, 0.01 inch; total for the month, 2.22 inches, that being 1.34 inch more than January, 1889. The month on the whole was very mild and sunless, the temperature on eighteen days being above 45°, whilst on some days it reached as high as 50°. There was an almost total absence of frost, the sharpest being 13° on the 1st, and 6° on the 3rd, 21st, and 30th, the only frosts of any note.—E. WALLIS, *Buntingford.*

— A WELL attended meeting of the READING AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION was held at the usual place on Monday last. Mr. William Lees presided. The subject foremost in the minds of the members was the death of Mr. Wildsmith of Heckfield. The Chairman made a graceful reference to this distinguished gardener, by whose death the Association would be the poorer, and British gardeners would feel that one of the best had been removed from their ranks. The members unanimously resolved that a wreath be sent from the Association, and several members were appointed as a deputation to attend the funeral. The Secretary was requested to write a letter of condolence to Mrs. Wildsmith. The subject for discussion was "Prevailing Difficulties with Certain Plants," introduced by Mr.

Jas. Martin. A magnificent specimen of *Cœlogyne cristata* was exhibited by Mr. W. Baskett, gardener to the President. The plant was 3 feet in diameter, and carrying nearly 300 flowers.

— A GARDENERS' MUTUAL IMPROVEMENT SOCIETY FOR CROYDON.—A meeting was held last week in the Old School of Art Room of the Public Hall for the purpose of inaugurating the above Society. Both amateurs and gardeners were represented. Mr. T. Wickham Jones was appointed to the chair, and briefly explained the objects of the meeting, which was to afford an opportunity for the interchange of ideas between nurserymen and amateurs in reference to horticultural matters. It was the outcome of a suggestion made by Mr. Bishop at the close of the last annual meeting of the Horticultural Society. A few of them had put their heads together and drawn up rules, which would be submitted, but the first thing would be for the meeting to decide whether it was desirable it should be formed. After a little discussion it was moved by Mr. Bishop, seconded by Mr. Butcher, and resolved unanimously, that there was room for such a society in Croydon, and that it should be formed, and called the "Croydon Gardeners' and Amateurs' Mutual Improvement Society." The rules were then submitted, which set forth that the Association should be instituted for the promotion and practice of the science of horticulture by holding periodical meetings, at which essays and papers should be read, and discussions introduced on all subjects connected therewith, and that a small library be formed for the information of the members. The members to consist of nurserymen, seedsmen, professional and amateur gardeners. Ordinary members' subscriptions to be 2s. 6d. per annum, and hon. members not less than 5s. The Society to be constituted by President, Vice-Presidents, Secretary, and a Committee of not less than twelve, six to form a quorum. Various other rules were passed in reference to the general management of the Club, and names were suggested for the offices of President, Vice-President, and Committee. The necessary arrangements for the first meeting were left in the hands of the Committee. Mr. S. Baxter, who had kindly undertaken the secretarial duties in connection with the preliminary meeting, was unanimously asked to continue in that office, which he accepted.

THE DEATH OF MR. WILDSMITH OF HECKFIELD GARDENS.

By the death of Mr. William Wildsmith British horticulture loses one of its most practical exponents. Not only was he one of the best all-round gardeners of the generation in which he lived and worked so well, but in all respects one of the worthiest of men. His mental and physical activity was remarkable, and no one was more ready than he to join in the furtherance of any good work. He was a member of the Fruit Committee of the Royal Horticultural Society, and a good and sound writer on gardening. He was, we think, a native of Yorkshire, and was raised from foreman to head gardener at Heckfield, as the successor of Mr. G. Tillyard. As some of his neighbours have referred to the death of this able gardener and good man we need say no more than that we mourn his loss, and tender to his widow deep sympathy in her bereavement. The funeral took place on February 4th in Heckfield Churchyard in the presence of over 200 spectators. Many beautiful wreaths were sent from friends. Noticeable amongst them were those from the Hon. Miss Shaw Lefevre; Messrs. Sutton & Sons; the Reading Gardeners' Association; the Birmingham Gardeners' Association; Mr. Lees, The Wilderness, Reading; Mr. W. J. Palmer, Reading; Mr. Turton, Maiden Erlegh; Mrs. Stanton, Park Place, Henley-on-Thames; Mrs. Crump, Madresfield Court; Mr. J. Allen, Swallowfield Park; Mr. A. Dean, Bedford; Mr. E. Molyneux, Swanmore Park; Mr. Rose, Lockinge Gardens; Mr. Trinder, Dogmersfield Park; Mr. G. Profit; and Mr. Tubb, Minley; one being sent also by Mr. J. Clayton, Grimston Gardens, Tadcaster, and Mr. J. Crook, Forde Abbey, Chard. Beside those persons represented as above, there were present Mr. Coleman, Eastnor Castle; Mr. Jones, Elvetham Park; Mr. Bell, Strathfieldsaye; Mr. Davidson, Highfield; Mr. Bowerman, Hackwood Park; Mr. Kneller, Malshanger Park; Mr. J. Martin (Messrs. Suttons); Mr. Robert Few; Mr. Legg, Bearwood; Mr. J. Pound, jun., Reading; Mr. S. Weaver, Oakley Park; Mr. Coombes, Inglefield; Mr. Heath, Hampton-in-Arden, Birmingham; and Mr. Basket, Reading.

It is being proposed, as a fitting tribute to the memory of one who took such a deep interest in the Gardeners' Orphan Fund, to raise a fund to be called "The Wildsmith Memorial Fund," with the object of placing a child on the Fund, such child to be known as the Wildsmith Memorial Orphan. As a preliminary the Committee of the Reading Gardeners' Association have undertaken the matter with a view to making the necessary arrangements.

Although not definitely settled, we understand the late Mr. Wildsmith will probably be succeeded by his foreman, Mr. H. Maxim, who has been in that capacity three years.

WITH very great regret we have to record the death of Mr. Wildsmith, the well-known gardener at Heckfield Place, Hants. He was

taken ill on Friday, the 19th January, which turned to congestion of the lungs and gastric fever, and to which he succumbed on Wednesday, January 29th, at the age of fifty-two. It may not be generally known that Mr. Wildsmith had been gardener at Heckfield Place for twenty-four years, and he has survived by only thirteen months his noble employer (Lord Eversley), whom he loved so well and served so faithfully. For a number of years Mr. Wildsmith was well known as a most successful exhibitor, but owing to an unfortunate accident of a few years ago, which impaired his health, he has latterly discontinued exhibiting.

As a horticulturist and gardener Mr. Wildsmith is too well known to need comment. As a gardener he had few equals and no superiors, for whatever he took in hand, whether flower gardening, fruit growing, vegetable culture, or Chrysanthemum growing, he was sure to do well. For years he was the winner of many very valuable prizes at the leading shows in the country, including the only gold cup ever offered for Chrysanthemums. Some of our most successful gardeners were foremen under Mr. Wildsmith, among whom may be mentioned Mr. Goodaere of Elvaston Castle, Mr. Crump of Madresfield Court, Mr. Turton of Maiden Erleigh, and Mr. Heath of Hampton Manor. Mr. Wildsmith's kindness and liberality were proverbial among his friends, who will long mourn his loss.—G. TRINDER, *Dogmersfield, Winchester.*

THROUGH the death of Mr. Wildsmith the horticultural world has lost one of its best supporters. Some years since, when returning home from an autumn exhibition at the Crystal Palace, he had the misfortune to meet with an accident by the overturning of his cart; since then he has experienced indifferent health. Mr. Wildsmith was one of our best Press contributors, having a high practical knowledge of the subjects he wrote about, he was able to convey his ideas to others in a clear manner. Besides this he was a capital judge of horticultural produce, especially in fruit and vegetables, taking as much interest in a small cottage show as in an exhibition of greater note, and was at all times willing to help struggling societies, often refusing to take a fee. Mr. Wildsmith was a man who was always ready to give advice truthfully, and on many occasions I have benefited by his kindness in this respect. As an exhibitor of Chrysanthemums he had secured the honour of winning the only gold cup ever offered for these flowers—that at Devizes some three or four years since. It was only during the last six years that he commenced growing these plants for exhibition purposes, but he was enabled to command success almost at first. I am afraid these few lines are but a poor attempt at expressing my feelings for the loss of one who was of such a kindly disposition, always ready to help others when the necessity arose, either in advice or otherwise. His welcome to visitors to Heckfield was always of the heartiest.—EDWIN MOLYNEUX.

In the course of a letter from Mr. E. Butts, who knew Mr. Wildsmith well, he says, "Flower gardening was considered Mr. Wildsmith's strong point, but I consider all his points were strong as a gardener, and I know that during his long period of service at Heckfield he converted a good number of raw articles into first-rate gardeners."

DISCUSSION AT SHEFFIELD.

BLOOMS DAMPING.

(Continued from page 73.)

THE next subject, the Chairman said, was the "Damping of Blooms," by Mr. Udale, who as an experienced grower, was quite competent to give information on the subject. Mr. Tunnington was to have opened the discussion, but he was rather unwell, and could not attend. Mr. Udale said it was a very debateable subject, and he was sorry Mr. Tunnington was not there. The question of the damping of Chrysanthemum blooms was certainly a very important one. Most exhibitors have been surprised and considerably annoyed at times to see their blooms damping. It may be that some florets here and there are the first to be noticed, and there are certain varieties which appear to be more liable to it than others, such as those with soft florets. One of the worst is Jeanne d'Arc. Another variety much subject to damping is Lady Hardinge, and the sport from it Mrs. Shipman. "What is the cause of damping? Possibly a combination of circumstances. Some say that it is through grossness, that plants have been over-fed. It is just within the range of probability that over-feeding may indirectly be the cause of damping. I am inclined to think that the fundamental cause of damping is the fear of using a little artificial heat. I should say the least of evils, rather than have good blooms spoiled by damp, is to turn on the heat. Damp frequently arises from a fall in the night temperature. Moisture is immediately precipitated on the florets, as the surface is colder than the surrounding atmosphere, and that I think is the chief reason. I must tell you frankly that in every case of neglect or fear of turning

on the heat, or both combined, I have had damping, but I find that when I have had a warm and buoyant atmosphere I have had no damping at all. There is still an advantage in having a little artificial heat because I think the flowers are bolder and of much better quality. My best flowers have always been cut from the plants that I have applied heat to night and day. It may be asked, How is it they "go" from the centre? I do not think that of itself would affect the argument I have just adduced. I believe the damp has entered into the hearts of the flowers before we knew it was there, and being there it is more difficult to dry even if we turn on artificial heat. Damping is more frequently produced by want of a buoyant atmosphere rather than by too gross feeding."

Referring to Mr. Udale's statement about Mrs. Shipman, Mr. Harrison said he was thinking what a good keeper Mrs. Shipman was. Three weeks ago he had a flower fully grown, and put it in an old hen house where water ran down the walls. He had been able to keep that bloom until three days ago. He would not have had an Avalanche if he had not have put a flower of that variety in the same place. A flower of Golden Beverley was fully grown a month since; it was cut and kept during that time, then exhibited. He partly attributed his success to putting buckets of fresh lime frequently into the place and thus absorbing the moisture. The place was constantly shut up close and dark. He found that damp appeared chiefly when the sun came out. He had always kept fire heat on the houses, but found most harm done by an hour or two of sun.

Mr. Udale thought that Mr. Harrison's remarks seemed rather to strengthen his argument that where there is an equable temperature there can be no deposition of moisture. Mr. Woodcock said his own opinions entirely coincided with Mr. Udale's that atmospheric influences cause the damping of blooms. At the Leicester Show, where they held a conference, one of the subjects touched upon was the damping of blooms. Mr. Petch interpolated some words to the effect that he did not believe that atmospheric influences caused damping, but that it was something amiss with the roots. Mr. John Wright, who was the Chairman, referred to an instance where some plants of the same variety stood together near hot-water pipes. One plant had been allowed to get very dry, all the flowers on that plant damped. He suggested from this fact that the finer roots having perished the weakest part of the plant—the flowers—had suffered first. The fine soft petals collapsed and fungus or mould took possession of the decaying parts; hence the so-called damping in that case.

Mr. Bacchus said that there were some varieties more susceptible to damp than others. In these he included Golden Dragon and Madame John Laing. He believed the cause of damping was taking the buds too late, which were never matured, and when they did open the sun had more effect upon them. He also mentioned plants standing directly near hot-water pipes being affected with damp.

Mr. Udale said he did not think he could have stronger support of his argument. It is a well known fact, and has been advanced strongly, that to avoid the scalding of Grapes the best way is to keep an equable temperature night and day. He said at first that the chief cause of damping in Chrysanthemums was the deposition of moisture on the petals through the falling of the temperature.

Mr. Wright's theory was interesting, but there appeared to be a confounding of cause and effect. He says that the mould is the result of defective root action; I believe that the mould is the outcome of the decayed petals. With regard to what Mr. Bacchus said about plants standing over pipes, the heat passed freely over the tops of the flowers, but we all know that the radiation of cold from glass during the night is greater than many of us suppose. He, therefore, contended that the heads of the plants should not be too near the glass, because moisture will be deposited where the temperature is lowest during the night. If the flowers are about 2 feet from the glass they will be safe. When a sunny day comes the more need there is for fire heat at night. Mr. Udale did not think anything had been adduced to shake his argument, though it is quite possible that damp may also arise from defective root action, and possibly Mr. Wright may not be wrong in his views.

Mr. Ledger said he would like to impart some information gathered from Mr. Tunnington on the question of damping. In answer to a question he had said, "My lad, damping comes in a night, and my opinion is that we lie in bed too long, and we want to be up before the sun and dry off the superfluous moisture. After housing place your plants well up to the glass until you get the bottom petals of the flower developed, then take them away to about 2 feet from the glass and keep up an equable temperature." He also said in answer to the question "Do you think feeding has anything to do with the damping of blooms?" that "Nothing ever passes through the roots that causes damping. We require a thorough circulation of air, the blooms not too near the glass, with a little fire heat constantly on, and it will be found that these are the best methods of avoiding damping." A question was asked of Mr. Udale if he had any ventilation on the house at night, to which he replied that he regulated that according to the temperature and the weather. Mr. Bacchus recommended cultivators not to trust to the thermometers, but to place their hands on the pipes and regulate the temperature by that.

CHRYSANTHEMUM MR. W. W. COLES.

THE bloom represented on fig. 19 is engraved from a beautiful photograph by Mr. J. Duncan Pearson of the specimen as it was grown at

Chilwell. It is probably one of the finest that has been seen of this very richly coloured and promising variety. The name is rendered Coules in

W. Coles, who was once employed under Mr. J. H. Goodacre at Elvaston, and now a successful florist at Cla. mount, Delaware, U.S.A.

FIG. 19.—JAPANESE CHRYSANTHEMUM MR. W. W. COLES.

some catalogues and Coler in others, but we think the one given above is correct. The variety, we are informed, was named after Mr. Walter

Mr. Coles is, we are told, one of the best Chrysanthemum growers and exhibitors in America, and his bright chestnut red patronymic

will probably be seen in many stands in England during the next autumn campaign.

THE FINANCIAL SUCCESSES OF CHRYSANTHEMUM EXHIBITIONS.

FOR some years past I have been annually told that Chrysanthemums have had their day; each year was said to be the last in which it would maintain its hold on the great flower loving public. My answer to this has always been the same. When the Chrysanthemum can be replaced by another plant as useful, as showy, as varied, as easily cultivated, and adapted for as many purposes, then I shall believe in its decline in popular favour. Within the space of four weeks over fifty exhibitions were held, and few can say that the receipts have been less than in the past. Many have increased their income far exceeding any previous year in the amount taken at the doors, which is very gratifying to those concerned, and promising well for future ventures. Local circumstances, no doubt, have a great influence on the success or otherwise of all societies—Chrysanthemum or otherwise—such as a suitable position in which to hold the show, a good subscription list whereon the Committee can rely if public support is not granted. There is not the slightest doubt that a spirited policy does more to command success than anything else. Sums previously unheard of as prizes appear to justify the wisdom of the outlay, proving a financial and horticultural success. I am aware that there are societies who could not reap the same reward, even if their schedule contained more tempting prizes than hitherto offered. I allude to towns where the population is small. Again, there are some which do not seem to possess a flower loving public.

High charges of admission are not favourable to success. Most of the leading societies are now aware of this and act accordingly. Some societies pride themselves on the select company present at their exhibitions, but the exchequer is unsatisfactory. Again there are some towns where Chrysanthemum exhibitions are financial failures; the Committee reckon upon losing £70 or £80 at each autumn show, although they have always been noted for the quality of the exhibits. This annual loss is maintained by the excellent summer exhibitions, which appear to be more popular with the townspeople. In the same county exactly the reverse has been the case—the autumn shows are the only ones which have paid their way, those held in the summer being a failure.

Some societies favour a three-days show, although I cannot call to mind at present more than three that do. This is an arrangement more of a local character than otherwise, with the exception that exhibitors require a little consideration, who do not as a rule regard an exhibition of three days' duration with favour. If societies who have three-day shows offer extra prizes as an equivalent, no harm is done to exhibitors. For the low scale of its charges of admission the Portsmouth Chrysanthemum Society has done wonders; as far as I know they hold a position unique in this matter. One of their features is the admission of the working classes during three hours—six to nine—on the evening of the last day at the low charge of 1d. As showing how much this is appreciated, as many as 9509 passed into the Drill Hall during the time named, and which realised no less a sum than £39 12s. 5d. During the short time that this large number of people passed through the Show not a single case of misbehaviour occurred. During the years 1888 and 1887 no less sums than £26 7s. 6d., £33 15s. 9d. was received during the same time and at the same charge. This year there is a substantial increase of £13. During the three-days Show 21,490 paid for admission, realising a sum of £240 5s. 5d. as against £154 0s. 7d. in 1888. The Exhibition opened at a charge of 1s., which realised £35 11s., while £38 9s. 6d. was taken at a 6d. charge on same day. The second day's takings show a marked change, as much as £97 10s. resulting from a 3d. charge as against £9 9s. 6d. of 6d. Add to this the fact that nearly 5000 school children were admitted free.

The Birmingham and Midland Counties Chrysanthemum Society has long enjoyed the distinction of being the leading Society in the Midlands, both in the quality of its exhibits and for the position which this Society has maintained. As many as twenty-nine exhibitions have been held. Last season this Society enjoyed the distinction of having offered the largest prizes of any society, which shows the spirit that prevails. The results of this prove the wisdom of the venture. Great numbers of people flocked to the Show, and on the second evening the doors had to be closed on account of the crush of visitors. It is not often that money has to be refused at the doors, but in this case it was so. The receipts at the doors were £277, which is £74 in excess of any previous year, and £108 more than 1888. As many as 15,500 people visited the Show in the two days. There is no doubt that offering such large prizes added much to the success achieved, which plainly shows that the end attained justified the means.

I have added York in my list simply to note how the financial success of this ancient Society compares with other large towns. It must be taken into consideration that York is the centre of an agricultural district, therefore it cannot be compared in the matter of finances with such large manufacturing towns as Birmingham. The cash taken at the doors during the three days amounted to £171 10s. as compared with £130 5s. 6d. in 1888, which is a satisfactory increase. Add to this a subscription and donation list of about £136, and we find this Society on a good foundation.

The Hull and East Riding Chrysanthemum Society is the worst favoured of any yet mentioned in regard to site for their Exhibition, the Artillery Barracks where the Show is held being too small. The N.C.S. Provincial Show held in conjunction with this Society no doubt added to the success of the undertaking. No society that I know of has ever offered so many valuable prizes at one show as at the last Show. The

receipts for last two years do not differ much, the totals being £212 17s. 6d. for 1888, and £241 2s. 6d. for 1889. Here the wisdom of high-priced admission may be questioned, as at 2s. 6d. each during the hours from 12.30 to 3 P.M. only thirty-nine people paid, while on the same day from five o'clock until ten the sum of £62 1s. was realised at 1s. admission. Even in two hours on the same day—from three to five—as much as £44 in shillings was received at the doors; while during the whole of the second day the charge was 6d., which realised a sum of £130 4s., making in all a total number of visitors 5208 who paid at the doors. Add to this 1805 visitors, subscribers, and those who previously bought tickets, charity children, teachers, &c., and we have a total number of a little over 10,000 against a total of 8734 in 1888.—E. MOLYNEUX.

KENT COUNTY CHRYSANTHEMUM SOCIETY.

THE second annual general meeting of this Society was held at the Rink, Blackheath on Thursday evening, January 30th. In the unavoidable absence of the President, the chair was occupied by S. S. Bryant, Esq. The report and financial statement tendered by the late Committee were unanimously adopted. The statement shows the Society to be working on a sound basis and carrying forward a balance of £20. The election of Committee and officers for the ensuing year having taken place, some considerable correspondence was read from members at a distance and duly discussed. The dates for the next Show were finally fixed for the 4th and 5th November, to be held at the Rink as before, and it was resolved that in addition to the liberal schedule of prizes of last year, that efforts be made to offer a special "Centenary" prize to mark this event in common with other Societies. The meeting terminated with cordial votes of thanks to the Chairman for presiding, and to the Hon. Secretary, Mr. H. A. Needs, for his valuable service to the Society.

HULL AND EAST RIDING CHRYSANTHEMUM SOCIETY.

THE annual meeting of the above Society was held on Wednesday, the 29th ult., when the report and balance sheet for the past year was passed, and officers and Committee elected for the ensuing year. The balance sheet showed that there was a profit of £8 15s. 7d. on the year's working of the Society, and the total funds in the bank £238 10s. 4d. The report referred to the Show in November last (which was held in conjunction with the second provincial Show of the National Chrysanthemum Society) as an advance on previous exhibitions held in Hull, which glances at the following comparative statement will show:—At the Exhibition held by the Society in 1888 the total number of exhibits of all classes was 220, while at the Show held in November last the number was 284, showing an increase of 64. The number of cut blooms at the last Show was 569 in excess of the number shown in 1888, while the value of prizes actually awarded, exclusive of challenge cups, was correspondingly larger, the amount in November last being £235 3s. 6d., as against £151 11s. 6d. in 1888, leaving a difference of £83 12s., a very large item. Mr. R. F. Jameson was unanimously re-elected Chairman, and Messrs. E. Harland and James Dixon Hon. Secs. It was announced that the next Show had been fixed for Wednesday and Thursday, November 19th and 20th, and the Judges would be Mr. J. Wright and Mr. Geo. Gordon. Mr. Geo. Bohn, C.E., one of the Vice-Presidents, presented to the Society a handsome silver challenge cup, value £20, to be competed for at the next Show, and received the thanks of the members.

COS LETTUCES.

WE have been trying for the past ten or eleven years to keep Lettuces through the winter, but they do not pay for the trouble. In the autumn of 1888 we placed out some 3000 plants of Bath Cos and Hicks' Hardy, and not more than 500 lived through the winter. Of the two the first stood the best, and on the whole was superior in quality. But there was no comparison between these and plants raised under glass in January, and planted out when ready on a warm border. They were scarcely a week behind those sown in autumn, and in addition to being of better quality there was fully double the amount of material in each Lettuce fit for use. We raised about 15,000 plants under glass last season of three varieties, and had good breadths of each. The varieties were Hicks' Hardy, Paris White, and Veitch's Superb. The last was decidedly the finest of the three, and is evidently a select strain of Paris White, or perhaps I may be more correct if I say has been carefully selected from that variety. It is a trifle earlier, larger, and stands longer without running to seed. Hundreds of plants from amongst that sown as Paris White were so much like Veitch's Superb that it was difficult to distinguish them, but it was clear that the selected form was the better of the two. Hicks' Hardy as a summer variety will not be grown again. It is large and crisp, the heaviest of the three, but it has large outside leaves, and a good quantity of them. When strongly grown it is prolific in making suckers, and when thoroughly filled up in the centre has started to run and bursts quickly. These are not its worst faults, it burns badly in the sun. The edges of the leaves turn brown and blotch, which destroys its appearance for market purposes.

To be successful with Lettuces when raised under glass every care is necessary to prevent the plants being crowded and drawing up weakly. If the seed is sown in gentle heat the boxes containing it should be removed to cool houses directly it has germinated. We place the boxes in a cool light airy Peach House, where the plants grow

sturdily, and are pricked off 2 inches apart into other boxes. When sturdy little plants about 1 inch high are secured they are placed in cold frames, and given air abundantly. The lights are thrown off when the weather is favourable, and are admitted to the frames at night, when there is no fear of frost. The boxes are stood out of the frames for a week or ten days to further harden the Lettuces before they are planted out.

To follow these seed is sown the first week in February, this time in boxes, which are placed in a cool house. The seed is a little longer in germinating, but the young plants do not run up an inch high almost at once, the same as they do when raised in heat. These should not be sown too thickly, and when they are ready for pricking out a low frame should be placed on a warm border, and the soil well broken up. With it should be incorporated leaf mould and potting shed refuse soil that has been passed through a sieve. We spread over the surface of the ordinary soil about 2 inches of this, so that the roots of the young plants will be in at first instead of the soil of the border. These grow slowly, but when planted out are ready for cutting by the time the majority of the earlier ones have been cleared from the ground.

For succession seed is sown in a frame on the same border a month later. The seed is sown on the surface of the soil of the border, and the plants are thinned out when large enough to prevent crowding. These can be pricked out, but we do not trouble to do so. A sowing is made outside during the last few days of March, and successional sowings are made at intervals of three weeks until the middle of June. Any rough low frames are good enough for the purpose of raising Lettuces. All that is really needed are a few boards nailed to stakes driven into the ground. If these are covered with lights they answer as well as frames of the best quality.

Young Lettuces are harder than many really think. Last year we were told our plants would all be killed, and we should have our trouble for nothing. The weather proved most unfavourable before they had taken to the soil, and although they were battered and broken by strong winds and storms frost did them no harm; two or three genial days started them into growth, and they never looked back afterwards. Those in open exposed flats did as well if not better than those on warm borders. On the whole, those in the open were very much the finest, but about a week later than those on a south border sheltered by a wall 6 feet high. The plants one yard from the wall were very much inferior to those at the front of the border, which is 8 feet wide; those near the wall were drawn.

To grow Lettuces well the ground should be deeply dug if possible in autumn, and when this cannot be done, as early in the year as it can be cleared of other crops. On that dug early manure should be wheeled during frosty weather, and left in heaps ready for spreading some time previous to planting. We prefer to do this and fork the manure in at the same time, breaking up the soil well as the work proceeds. All the land that was turned up roughly last year became thoroughly pulverised and was in excellent condition for planting after it had been forked over and left for two or three days. Lettuces delight in well worked soil, and if the surface has become fine from exposure they are easier to plant and grow more quickly than when the soil is rough and lumpy at planting time.

Manure in a well decomposed state should be used. Lettuces dislike fresh manure, it is too hot and forcing for them, especially for plants that have to endure drought and bright sunshine. The roots take to rotten manure freely, but not when it is practically fresh. If it must be used in this condition it should be turned into the ground as it is dug or decomposed by frequently turning the heap. This, however, is too costly an operation, and does not improve the manure sufficiently to cover the cost of turning it.

Shallow drills are drawn 1 foot apart as planting proceeds, and the plants placed 1 foot apart. In planting care is needed to place the roots straight down—that is, open the hole sufficiently large to place in the roots without doubling them. Those from boxes generally plant with balls, and are planted with small trowels. After the plants commence growing the hoe should be run through the ground to loosen the surface and render it fine. The more the hoe is used the quicker the plants grow, and are ready for cutting fully a fortnight earlier than those that are only hoed to keep down weeds. It is surprising how one or two applications of soot strewn over them in their early stages during showery weather assists them to make rapid growth. This should be done while the plants are quite small.

During hot dry weather Lettuces do better on borders or flats that are not freely exposed to the sun. North borders can be selected, and mulching can be practised by those who grow a few plants only, but those who grow large breadths for the market cannot well practise these methods. They are not really necessary if the ground has been well worked, liberally manured, and the hoe is constantly going amongst them. When the surface is dry and fine they grow quickly even in dry weather.

Whether grown for home use or the market Lettuces pay well for the most careful treatment in their early stages, well worked ground and the most liberal of treatment. When they are grown for the market they should be pulled up, not cut off, for they keep fresh nearly double the length of time.—W. BARDNEY.

LIQUID MANURE FOR RESTING PLANTS.—The value of liquid manure occasionally to plants during their resting period may be clearly seen when they make a fresh start, as they grow more vigorously in

consequence, and often do not need repotting if the feeding is continued during their growth. Those that do require to be repotted are equally improved by the liquid manure previously given, as the stronger the growth the more quickly the roots take possession of the fresh soil.—A YOUNGSTER.

THE BRITISH FRUIT GROWERS' ASSOCIATION.

AN adjourned annual general meeting of the above Association was held in the Horticultural Club Room, Hotel Windsor, Victoria Street, on Thursday, January 30th, at 3 P.M., T. Francis Rivers, Esq., in the chair. The principal business was the consideration of a code of rules based on those originally drawn up, but which have been found to be inadequate for the purposes of the Association. After considerable discussion it was duly resolved that the following rules should be adopted and printed.

RULES OF THE ASSOCIATION.

1. **TITLE.**—The title shall be the "The British Fruit Growers' Association."

2. **OBJECTS AND METHODS.**

A. *Objects.*—The objects of the Association shall be to promote the profitable culture of fruit in Great Britain and Ireland, to facilitate the distribution of fruit to consumers, and to disseminate practical information on these subjects.

B. *Methods.*—The Association shall endeavour to effect these objects by the means of meetings and conferences in the metropolis and the provinces, by the collection of reliable information, by the publication of such reports and essays as the funds may permit, by securing the adherence of local societies, by the award of prizes, medals, and certificates to successful cultivators and those who have assisted in the extension of knowledge in fruit subjects, and by such other methods as the General Committee shall determine.

3. **MANAGEMENT.**

A. *Officers.*—The management of the Association's affairs shall be entrusted to the following officers:—A President, Vice-Presidents, Treasurer, Chairman of Committees, Vice-Chairman of Committees, and an Honorary Secretary. All the officers shall be *ex-officio* members of the General Committee, the Chairman, Vice-Chairman, Treasurer, and the Hon. Secretary being *ex-officio* members of the Executive and all Sub-Committees. All the officers shall retire annually, but be eligible for re-election.

B. *Committee.*—The General Committee shall comprise forty members of the Association (exclusive of delegates from affiliated societies as provided in Rule 5), ten of whom shall retire annually, but be eligible for re-election. The members shall be proposed, seconded, and elected at the annual general meeting, and after the business of the annual meeting, or at the first subsequent meeting, the General Committee shall elect from amongst their own members an Executive Committee of fifteen members, to whom the arrangements for the current year will be entrusted.

4. **ELECTION OF MEMBERS.**

A. *Subscriptions and Donations.*—Any person who desires to become a member of the Association shall be proposed by one member and seconded by another at any meeting, and if duly elected shall, on payment of his subscription, be entitled to the privilege of membership in accordance with paragraph B of this rule. Donations of not less than 5s. shall confer the same privileges (for the current year) as subscriptions, if the donor so desire. Elections shall be effected by ballot or by show of hands, a majority being required to elect an opposed candidate. This shall apply also to members of the Committee.

B. *Privileges.*—1. Subscribers of 5s. per annum shall be entitled to personal admission to all general meetings and conferences, to a vote at the annual and other general meetings, and to a copy of the Association's annual report. 2. Subscribers of 10s. shall be entitled to a transferable ticket of admission to the meetings specified in section 1, to a copy of every publication issued by the Association, and all privileges named in section 1. 3. Subscribers of one guinea shall be entitled to the privileges named in sections 1 and 2, also to such assistance as the Committee can render in naming varieties of fruit, and to advice by letter on matters connected with fruit culture. Subscriptions for the current year shall be due at the date of joining the Association, and subsequently annually on Jan. 1st, and no member whose subscription is unpaid shall be entitled to take part in the proceedings or to the other privileges of membership.

5. **AFFILIATED SOCIETIES.**

Horticultural and other provincial societies concerned with fruit culture shall be affiliated with the British Fruit Growers' Association on the payment of an annual subscription of 10s. The affiliated Society will receive a transferable ticket of admission to all conferences, and may appoint a delegate as a member of the General Committee. A copy of each of the Association's publications will be sent to the Secretary, and two of the Association's certificates to be awarded for meritorious exhibits of fruit, for well managed fruit gardens, and for presentation to those who have displayed proficiency in fruit culture.

6. MEETINGS OF THE ASSOCIATION.

A. General Meetings.—General meetings shall be held as often as the officers may deem necessary, and such a meeting can also be called at any time on a requisition stating the object, and signed by twenty members, being placed in the hands of the Hon. Secretary at least fourteen days before the date of the intended meeting. The general annual meeting shall be held in January. No new rule or rules shall be added, or the existing ones altered, except at a general meeting.

B. Committee Meetings.—The General Committee shall meet at least twice a year, and the Executive Committee as frequently as necessary. At all meetings five shall form a quorum.

C. Conferences and Special Meetings.—Conferences upon fruit subjects and special meetings for discussion shall be arranged to be held in the metropolis and provincial towns in connection with horticultural shows or otherwise, as convenient or desirable. The whole of such arrangements will be undertaken by the Executive Committee of the Association or in conjunction with the local Committee. Papers upon special subjects will be read, and questions submitted for discussion. All papers read by members at the meetings shall become the property of the Association, unless otherwise arranged, and shall be printed or disposed of as the Executive Committee may decide.

7. FUNDS, EXPENSES, AND ACCOUNTS.

All subscriptions and donations shall be paid to the Secretary, who shall forward receipts. At each annual meeting the members shall vote a sum of money for the working expenses of the year, and that shall not be exceeded except by the authority of a general meeting. The Hon. Secretary shall be empowered to retain the sum voted for the discharge of the expenses incurred. All monies received beyond that amount shall be placed in the Treasurer's hands and will be dealt with as a general meeting of members shall direct, in the furtherance of the Association's objects. The accounts of the Association shall be kept by the Hon. Secretary, and audited prior to the annual meeting by two members of the Association appointed by the Executive Committee.

Mr. T. F. Rivers was then elected as Chairman of Committees and Mr. G. Gordon as Vice-Chairman, the following being the completed list of Officers and Committee for the year as elected:—

President:

Lord Brooke, M.P.

Vice-Presidents:

C. de Laune Faunee de Laune, Esq.

Robert Hogg, Esq., LL.D.

Charles Whitehead, Esq., F.R.A.S.

Philip Crowley, Esq., F.R.H.S.

E. J. Bailie, Esq., F.L.S.

Treasurer:

A. H. Smee, Esq.

Chairman of Committees:

T. Francis Rivers, Esq.

Vice-Chairman:

Mr. George Gordon.

Honorary Secretary:

Mr. Lewis Castle.

General Committee:

Mr. J. Austen

" J. Wright

such a meeting, and to issue tickets to those specially interested in the subject. A representative Committee was formed, with Messrs. Castle and Earley as Hon. Secretaries, and a programme for a two-days conference was ultimately issued. This took place on September 7th and 8th, 1888, Mr. T. Francis Rivers presiding. There was an exceptionally large attendance, and the meeting proved an unqualified success. At the conclusion of the proceedings a resolution was proposed to the effect that it was desirable a Society of Fruit Growers should be formed, and that the Executive Committee of the Conference be entrusted with the preparation of a scheme for carrying this into effect. This was duly seconded and unanimously adopted. The Conference was also adjourned until October.

Before the second meeting was held a scheme had been devised for the institution of a Society under the title of the British Fruit Growers' Association, and at the adjourned conference in October 1888, this was announced and accepted. The first general meeting was held in the Crystal Palace, October 18th, 1888, at 6 P.M., Mr. John Laing, in the chair, when the Society was duly organised, members, officers, and Committee elected, and rules adopted. A general meeting was also held in the Royal Aquarium, Westminster, on November 8th, 1888, to discuss railway rates in relation to fruit transit, and much important information was evoked, but it was subsequently found that the funds of the Association would not permit an adequate inquiry in the matter.

On October 10th, 1889, a well attended Conference was held in the Crystal Palace, where Mr. T. F. Rivers presided, and papers were read by Mr. J. Wright and Mr. G. Gordon, followed by considerable discussion of an instructive character.

It is gratifying to the Committee to announce that these conferences and meetings have been freely reported in the daily and horticultural papers, and large numbers of letters have been received from many districts in Great Britain expressing hearty approval of the work of the Association in diffusing reliable information in fruit culture. The Committee also have abundant assurance that the conferences have assisted greatly in directing attention to fruit culture for profit in this country, and in helping to dispel the erroneous ideas, too freely circulated, respecting the enormous returns obtainable from a small capital employed in fruit cultivation. Much harm has been done by ill-informed advisers, for while fruit growing can be made to pay a fair profit for the labour required, the land occupied, and the capital expended, this cannot be accomplished without practical knowledge of the work, starting with a carefully considered scheme, and sound judgment in carrying it out.

The Association hopes to extend the sphere of its labours during the year 1890, and a programme is now under consideration. To enable this to be carried out satisfactorily, however, a material addition to its financial resources will be necessary. Owing to the low rate of subscriptions it is only by a great increase in the number of members and by donations from those interested in the Association that its object, the extension of profitable fruit culture, can be accomplished. During the years 1888 and 1889 the total expenditure was £18, leaving a small balance in hand.

The Committee also desire to state that the Association is not intended to act in rivalry with any other horticultural society or institution engaged in similar work, but rather to co-operate where possible, and to this end the support of provincial societies is invited.

The consideration of a number of letters containing propositions respecting the holding of meetings and conferences in the metropolis and the provinces occupied some time, and several members were elected. The working expenses of 1890 were estimated not to exceed £30, and this sum was voted in accordance with rule 7. The General Committee held a meeting subsequently, at which fifteen members were appointed the Executive Committee:—Votes of thanks to the Chairman, and to the Horticultural Club for the use of the room, closed the business of the meeting.

AM I IN IT?

AMONGST the manifold and great writers of the present day, and the encouragement they are receiving, an old fogey like myself, who formerly bore the burden and heat of the day for the mere love of the thing, and who always has been, and is now practically at work, may perhaps be excused if he thinks it a little hard to find himself shut out in the cold.

HALL FOR HORTICULTURE.—I have read that claimants are arising as being first to recommend a Horticultural Hall, now, and let me add always, so much wanted. For myself I should have been glad to have seen the structure years ago, and I did advise my best to have the Exhibition building of 1851 retained for the purpose upon the site where it then stood; and I still maintain a structure of the sort, adding a Horticultural Club and Hall, and leaving out the manufacturing and shop element, is what is wanted. I happened to alight upon an old copy of a letter I wrote in 1867, when the present Horticultural Club was very young, and we used to hold our meetings at Anderton's. I pin it to the title page of the *Cottage Gardener* for your perusal, to show how the idea cannot be claimed now as being original; and as I hope anything likely to be able to push this matter on may be useful.

ORCHARDING.—Perhaps you may think it well to reprint the orchard parts of the "Gardener's Almanac" entire, and at once, in the *Journal of Horticulture*, it may help again even now to push the work

Several members were also proposed for any vacancies that may occur during the year.

The appended report of the Committee was submitted and adopted.

REPORT FOR THE YEAR 1889.

In presenting the first report of the British Fruit Growers' Association, the Committee consider it desirable to review the circumstances which led to its formation. Early in 1888 it was proposed by Messrs. George Gordon and Lewis Castle that a conference of fruit growers might be held at the Crystal Palace, Sydenham, in conjunction with the September show of that year. The manager of the Crystal Palace cordially entertained the idea, promised to provide a suitable place for

along. I have only now just completed planting another new orchard, the stocks of which I raised from pips, grafted them myself experimentally (I am nothing if I am not experimental) with local Apples, and I hope to be spared another year or two to let you know the result. And now for something new on my part.

MEMORIAL TREES, A SOPORIFIC.—Great men have left it on record how to obtain sleep. The late Bishop of Oxford (Wilberforce) was the last I believe. His soporific was to count up to a certain number of figures, and repeat till Morpheus came; dry work, and uncertain. Now, many friends of mine through my request have presented me with memorial trees, both evergreen and deciduous. I have them planted around my place in sympathy. "When in the night I sleepless lie" (and I assure you I am not exempt from the troubles of this world) I walk and talk in mind around my living representative keepsakes, calling them by their own and their donors' names, thus:—*Cupressus Lawsoniana*, poor Woodbridge; *Taxus variegata aurea*, poor Howe; *Cupressus Lawsoniana viridis erecta*, poor Wildsmith; *Thuopsis borealis*, friend Bell; *Pinus austriaca*, friend Jones, must reluctantly trim off bottom branches; seedling purple Plum from Green Gage (excellent), friend Stroud; *Thuia Lobbi*, friend Coombes, must be top-dressed with some fresh loam; and so on, and as I have above 100 mementos which I can dwell upon and admire in my mind's eye I can generally reckon upon obtaining unconsciousness before I have got one-quarter through them, and upon the next sleepless night I begin where I left off, and so shake hands as it were with all my friends without neglect of any, and "so He giveth his beloved sleep." Let our friends try this plan.—**ROBT. FENN, Cottage Farm, Sulhamstead Abbots.**

[Our old friend is decidedly "in it," and on one part at least is very much awake. His proposition for retaining the Exhibition building of 1851 as a centre for national horticulture appeared in the *Cottage Gardener* of April 22nd, 1852. His proposition that we reprint "at once" his orchard notes from the "Gardener's Almanack" (1852) must have been made when under the soporific influence of his memorial trees, and if he rubs his eyes a little he will see that monthly instructions from January to December on seasonable routine could not all be in season "at once," good as they may be for the several periods of the year; but we find an article on small fruits that reads as fresh as the day it was written, nearly forty years ago, and which we will reprint for the perusal of present day readers, and those of them who are acquainted with the genial author will rejoice that he is still engaged in the youthful work of making experiments. If his new Apples prove as good as his new Potatoes he will deserve doubly well of his country.]

DRESSING ROSE BLOOMS.

It is not my intention to prolong this correspondence. I wrote to further the best interests of the Rose and her exhibitors. Your readers will judge whether "D., Deal," in his last letter does or does not simply beg the question. It may be that in this instance a certain legal maxim is being adopted—viz., when your case is weak abuse the plaintiff's attorney.—**J. H. P.**

MANNERS AND CUSTOMS—A CATALOGUE COMMENTARY.

(Continued from page 65.)

Mrs. Barker (Laxton, 1876).—Of Victor Verdier race, following the manners and customs of its tribe; perhaps the lightest of them in colour, of excellent shape, but not very lasting.

Mrs. Harry Turner (Turner, 1880).—Of strong good characteristic wood and foliage, not much injured by mildew or rain. This is the brightest of all the deep crimson Roses, and would have a great reputation if it had but lasting qualities. Unfortunately the centre is weak, and it will not stand, so that it is next to impossible to show it. A free bloomer and fair autumnal. Sure to attract attention in the garden by the splendid glow of its colour.

Mrs. John Laing (Bennett, 1887).—One of the very best; apparently from similarity of wood and growth a seedling from François Michelon. One catalogue describes it as "in the way of Madame Gabriel Luizet," but this is surely a slip. Fine hardy growth and foliage; not liable to mildew or injured by rain. In the matter of "coming good" it may, I think, fairly dispute the palm with Marie Baumann, for it always comes well shaped with me, even in the autumn, and though a new Rose it has stood and successfully passed the tests of a cold, wet, late summer, and a hot early one. In every quality—petal, fulness of centre, shape, colour, lasting qualities, size, and freedom of bloom in summer and autumn it seems to be first rate. It is hardy and strong in constitution, and, in fact, I am puzzling my brains to think of a weak spot or deficiency of manners in any respect, but in vain. Go up to the top of the class, Mrs. John Laing, among the choicest of Rose queens.

Paul Neyron (Levet, 1869).—Alphabetical order is strictly impartial, and we have here, following a gold medallist, one of the "best abused" of Roses. Of extraordinary strong growth and foliage, little injured by rain, and almost entirely untouched by mildew, with enormous blooms

of grand stout petals, Paul Neyron is yet justly considered to be too coarse and wanting in delicacy and symmetry for a florist's flower. The outside world have often (most unjustly) taunted Rose exhibitors with going in for mere size, it being their idea, I believe, that Edouard Morren and Paul Neyron are the special darlings of our hearts. I remember on one occasion a worthy gentleman sending six Paul Neyrons with considerable confidence to a show in his neighbourhood, and instructing his gardener to pick out the "biggest." They formed a most ludicrous sight against other well shown Roses; so utterly overblown, shapeless, and discoloured that, as "Duckwing" observed, a cow would have turned up her nose at them. It may perhaps be said that this was mere local ignorance, but I also remember one or two articles from the editor's pen in a weekly journal of very high repute, in which the sorts raised and shown by exhibitors were condemned as being chosen for mere size and blowiness, and as worthy of the terrible title of the articles in question, "Ugly Roses." Paul Neyron is occasionally shown in fair form, and would be oftener thus exhibited no doubt, but rosarians have felt the weight of the unjust stigma alluded to above, and poor Paul Neyron and Edouard Morren have become bywords among them. Fairly free flowering and pretty good in autumn, with its strong growth and constitution, and especially with its remarkable immunity from mildew, the evident use of this Rose is as a seed parent to instil vigour and size into refined but weakly sorts. Mons. Levet has already made use of it in this way, as we know, and Paul Neyron lives again, with vastly increased reputation, in Ulrich Brunner.

Penelope Mayo (Davis, 1878), syn. *Duchesse de Caylus* (Verdier, 1864).—Rather weakly in growth and foliage, with wood of very distinct appearance, and not much liable to injury from mildew or rain. The blooms come fairly well, small, but sweet scented, of perfect form, good centre and bright colour. It still keeps its place, but a Rose which is weakly in growth, not good in free flowering or autumnal qualities, and decidedly below par in size, will fall out of the lists, I expect, before long.

Pierre Notting (Portemer, 1863).—Of very vigorous strong growth with extra large fine foliage. Rather liable to mildew, and will roa without opening in wet weather. This Rose "comes" very badly as a rule, being slow in opening, and showing a great hollow in the centre right down to the eye even before it does expand. The plants are passee by as hopeless again and again; then, with some mysterious climatic change (for fine weather alone will not do it), towards the end of the season the blooms sometimes begin to open properly when all the strongest are over, and we see what a truly grand flower it can be when it chooses. Though still weak in centre and in endurance, it is excellent in shape, colour, fragrance, substance, and size, and "bad manners" alone keep Pierre Notting from a very high position. It is aggravating to see such splendid shoots produce nothing but ill-formed hollow lumps, which can hardly be called Roses, while the plant has such fine possibilities within its reach. Free flowering but not a good autumnal, the second crop of blooms being seldom of any value. The violet shade on the outer petals has always appeared to me one of our nearest approaches to blue; and appearances seem to show that the first blue Rose (when will it come?) will be a dark one.—**W. R. RAILLEM.**

(To be continued.)

IMPROVING AN OLD ORCHARD.

RESPECTING the application of liquid manure to fruit trees in winter, I can add a little testimony. Eleven years ago last August I took charge of an old orchard. The trees were in a bad condition, and the fruit they produced did not always satisfy the cook. Some of the tree stems were 9 to 11 inches in diameter, quite hollow in the centre, and birds reared their young in the holes every spring or summer, and I was told that the trees only had a crop every alternate year. They were standards, planted 15 feet apart, though 40 feet by 30 feet would be a great deal better, with nuts and bush fruits between, also a few Farleigh Damsons planted at intervals, that would give the Apple trees a chance of benefiting the occupier. The orchard in question was sheltered from strong winds. The depth of soil was only 5 to 9 inches, on limestone, for 18 inches or 2 feet, in thin, flat pieces in layers; below that the stones were thicker. Many of the tree heads were crowded with wood, some of the branches crossing each other. The stems and branches were also covered with moss, and some of them with Ivy climbing. The causes of the defects, I considered, were overcrowding the heads and poverty at the roots.

In starting for improvement we thoroughly thinned the branches, carefully smoothing the wounds with a carpenter's chisel. The cuts were then painted over with a composition of clay, cowdung and soot. The stems and large branches were scraped, and when finished we gave a good lime-washing, with a little soot added to kill the moss on the small branches. A labourer went with a wheelbarrow of lime (slacked), with a shovel threw the lime up amongst the branches.

There happened to be a good liquid manure tank with a pump in the crew yard, and with a large barrel in a cart a man with a strong pony carted out the liquid in frosty or wet weather all the year round. We gave a load to each tree; when all the trees had been supplied we began again for about six or seven years. After the trees had four or five years such treatment some of them carried crops of fruit that would not have disgraced anyone. Some of the fruits with other varieties added did good service on the show tables for more than one year. That was not all, for instead of the trees bearing a crop of fruit every alternate

year, as they once did, they gave a good crop every year. They did not make much wood, and I believe that if fruit trees had plenty of room on a stone bottom, sheltered and well fed at the surface, that they would bear a good crop of fruit every year if they had only about 1 foot of soil to root in. Yet with all their improvement the old trees did not give the same satisfaction as young trees planted about the time the improvement began. Young trees properly planted and well fed from the surface give grand results. My idea is old trees for quantity, young trees for quality of fruit.

I knew a tree of the Blenheim Pippin Apple which is growing in the centre of a cesspool. The hole is about 6 or 7 feet in diameter, and acts as a catch pit for a drain that takes the refuse water from five or six cottages. It is about 18 inches deep in the centre, where the neck of the tree is, on rocky ground the water draining away leaves the mud behind. As a rule it is only cleaned out once a year, then there is often 4 to 6 inches of mud surrounding the stem of the tree. For all that the tree looks healthy, the leaves are a fine green colour, and a good crop of fruit is borne each year.—ONE DISENGAGED.

SEASONABLE HINTS ON HARDY FLORISTS' FLOWERS

THE very remarkable season through which we are passing must have its influence on all flowers, and amongst them those which are ordinarily known as florists' flowers, a term which I use in a much more restricted sense than many do. According to some, everything that is grown in collections comes under that term, while hardness seems to be no characteristic worth considering, for I find Dahlias included in the designation, although the first frost turns them black. I have no doubt that the question which perplexes many growers, or rather exhibitors, is,—Shall we suffer for all this mild weather by-and-by, or shall we have a very early season? At present there is every indication of the latter, but we may expect the inevitable cold east winds of March and April will probably alter the entire aspect of things. Of all idle things that of prophesying about the weather in our climate is the very idlest, and so we must act for the present and hope for the best.

AURICULAS.—The last time that I mentioned these I said that I had never had so little autumn bloom, but the excessively mild weather that we had at a time when we might reasonably look for snow and frost has roused many of those plants which were resting out of their sleep, with the result that I have now quite a number, I am sorry to say, which are flowering. This is the more to be deplored, as it is impossible to look for a bloom for them at the proper season. There is some hope when a plant blooms in September, but never when it blooms in January. I cannot quite agree with Mr. Douglas that frost does not injure the Auricula. Perhaps not, as far as the vitality of the plant is concerned, but it used to be held by the older florists that although it might not affect the vitality of the plant, yet that it did a considerable amount of damage by crippling the flowers, and that many a rough bloom was to be attributed to this cause. He seems to think that it does no injury. It is a matter about which there is no positive proof, and so each may keep his own opinion. I have heard of one enthusiast of former days who, knowing that the Auricula was of Alpine origin, opened his frames during a fall of snow, with the result of the loss of his collection.

At this season it used to be *en règle* to top-dress the Auriculas, taking out the surface soil to the depth of an inch, and filling in with fresh and rich compost, but the modern system of culture saves us all this trouble. I remember when it used to be a heavy piece of business, and I think it is a great matter to be spared it. I have not yet put my small collection into their blooming quarters (a pit) without any heat, but intend to do so at once. The pots will then be manured singly, all dead foliage plucked off, any offsets that are large enough removed, the surface of the soil moved, and if there are any traces of woolly aphis round the stems they will be removed; but their existence anywhere else about the plant does not trouble me much now, although it did formerly, and I have lost many a plant by trying to cure it when I ought to have left it alone, for I cannot find that it does any material damage except when it attacks the collar or neck. As the plants will now be moved into a more sunny position they will require during favourable weather more water, and air should be given as much as possible by night as well during the day when the weather is not frosty. The Auricula loves fresh air, although it is wonderful how it thrives near to towns, although one of our largest northern growers for sale, Mr. Jonathan Booth of Fallowfield, tells me he has been obliged to give them up owing to the increase of buildings around his garden.

CARNATIONS AND PICOTEEES.—These are looking very well, the foliage having that blue glaucous look which is so indicative of health. They have been kept as dry as possible, and I see no spots on the leaves and very little dead foliage. They will remain in their present quarters (frames) for another month or six weeks, and in the meantime everything should be got ready for potting. The pots should be washed and stowed away, the compost well turned over and hand-picked, so that all worms, and specially that destructive one the wireworm, can be carefully picked out. The pieces of turf should be pulled to pieces, as often he lurks within. The compost should be well turned over. Mine is placed under a glass roof open on all sides, it is thus protected from the rain while it has the wind playing upon it continually. It is well to look to labels, and where these have by use been worn or the writing obliterated fresh ones should be substituted. An amateur who loves his flowers is always desirous that they should be correctly named, even

though no appreciative eye but his own rests on them. This is unfortunately my position, and save ourselves there is hardly anyone who enters my garden who knows the difference between a Carnation and a Picotee. The pleasant chats which growers have one with another in the neighbourhood of the metropolis are denied to us who live in rural districts.

GLADIOLI.—This very remarkable season has somewhat interfered with growers of this grand autumn flower. Where care has not been taken in storing them they have started into growth, while it has been almost impossible to turn over the beds owing to the constant rain we have lately had, and it is far better to leave the beds alone than to attempt to do anything with it when the ground is at all sticky. I have always advocated the plan of laying the roots out singly, so as to prevent their growing, and am to-day an example of those people who preach but do not practise, at least in this way. All of our roots I treated in the open frames which I have used for many years, and which I have described in the Journal, but I this year received some from Fontainebleau, and of some there were three or four corms. They were in brown paper bags, and seeing how beautifully they were harvested, and being very busy at the time, I put them away in the bags. The other day I went to look at them, and great was my horror to perceive some had shot out shoots an inch long, and others had begun to emit roots. I did not trouble myself, but those which had started I felt must be attended to. The ground was too wet to plant them, so I determined on placing them in small pots, to be turned out afterwards when the beds are planted. I found that it was the early flowering varieties, such as Shakespeare, Adolphe Brongniart, Sceptre de Flore, and Arrière Garde which had started.

PANSIES.—I have just reported some, and they seem to have passed through the winter very well, having been kept as hardy as possible and given plenty of air at all times; as the one danger with these is damping off, they have been kept somewhat dry, but not allowed to flag. I have long since given up the Show varieties, and only grow the Fancies, which are now so large, smooth, and finely shaped, and certainly more hardy and more easily propagated. Like the Auricula and Carnation they enjoy plenty of air, and are impatient of damp.

RANUNCULUS.—The time for planting the Persian varieties will now be at hand. The ground is now with us very wet, and should frost come it will be great advantage to it to turn the soil over, otherwise it had better be left alone. My time for planting is about the 12th of February. Some care, as I have frequently stated, is required in planting them, about 1½ inch in depth, the rows to be about 4 inches apart, and the roots to be planted between 4 and 5 inches apart in the rows. A little sand may be sprinkled over the roots when planted, and they should be very firmly pressed into the ground, as they are so likely to be disturbed by earthworms.

ROSES.—It has been a wonderful season for the Rose. The tops of the shoots are in many instances quite green, but I do not see any pushing out of the lower buds. Tea Roses took wonderfully well. Whether we shall pay for all this by-and-by is of course all uncertain, and it will be well to let the mulching remain on the beds so as to protect them from frost if it should come now. A number of Tea Roses did not reach me until it was too late to plant, and they are now heeled in, and will not be planted until March. This is the plan which is recommended for cold situations, but my adoption of it has been a matter of necessity, not of choice.

TULIPS.—I do not profess to grow these as a florist ought to do. I have some varieties, but I never take the trouble of planting them in rows according to height and colour, but they give me a good deal of pleasure for all that. Most of the bulbs I obtained from Holland I have been obliged to discard, as the flowers were either ill shaped or stained at the base, for whatever the Dutch may have been in former days, they are behind the English growers now. The bulbs will soon be putting their heads above ground, but they are very hardy, and do not require protection.

Let me again repeat that I look at these flowers, not from the exhibitor's point of view, but that of the amateur who delights in his garden and enjoys his flowers for their own sake.—D., Deal.

SULPHIDES AS FUNGICIDES.

IN the *Journal of Horticulture*, January 2nd, page 2, Mr. Tonks describes the way bi-sulphide of calcium is made. Having used this excellent fungicide for several years and with the best results, perhaps it might be interesting to some of your readers if I explain the way I make it.

Mr. Tonks points out the difficulty of getting fungicides to adhere to the fungus, and this was just the difficulty I experienced. My first trial with it was four years since. I had a quantity of pot Roses badly affected with "Orange fungus or rust." I tried everything usually recommended for such maladies such as flowers of sulphur, paraffin, Gishurst compound, &c., but none of these had the desired effect, or indeed any effect whatever, and this disease spread to every plant I had, and before the wood was half ripened every leaf was off.

I forget just at this moment where or how I came by the receipt which Mr. Tonks has so kindly given, but at all events the one I use is identical, only I make larger quantities, namely—3 lbs. of lime, 3 lbs. of sulphur, 3 gallons of water, and I strain this through muslin and bottle off, and, as Mr. Tonks says, this is a bright yellow colour. I use a small thumb pot full to 3 gallons of water. When I first used this I found that it did not stick to the fungus, therefore it was not

absolutely effectual; it checked it considerably, but I was not satisfied and determined to try a little softsoap, which I dissolved in warm water, 2 ozs. to 3 gallons of water with the sulphide, this I thoroughly stirred and mixed together. I turned the pots on their sides and syringed the Roses thoroughly with it, and since that time I have never seen the slightest suspicion of "Orange fungus" on my Roses.

Whether the softsoap caused the sulphide to stick to the fungus or not I am not prepared to say, but perhaps Mr. Tonks will tell us that, but the above are the plain facts. I have no doubt that it would have the same good results on Hollyhock affected by the fungus.

There is only one objection to its use so far as I know, and that is when used in houses it will discolour the paint, but as Mr. Tonks says, this can readily be removed by a little warm water, and probably the syringe would fetch most of it off if charged with warm soapy water. It is the best remedy for the common mildew whether on Roses, Vines or other plants subject to it I have used.—T. A.

THE FRUIT QUESTION.

THE following report from the *City Press* contains the substance of the speeches delivered at the banquet of the Fruiterers' Company that was briefly referred to last week:—

The MASTER (Sir James Whitehead, Bart.) said agriculture and horticulture went hand in hand, and whatever affected one must more or less affect the other. Agriculture in these days required to be supplemented to some extent by the cultivation of fruit. He was not going to say that every farmer could make a profit of his farm by the cultivation of fruit; but this he did say, that every farmer, if circumstances favoured him, might by the cultivation of fruit add something to his income, and he thought, too, that if the farmer was able to add something to his own income, he might also add something to the income of the landlord and the labourer. So far as the Fruiterers' Company was concerned he could assure them their aim and endeavour would be to promote the cultivation of fruit in this country. It might be that in the past initiation of the Company there was a feeling of protecting the people in regard to foreign imports of fruit, but they had advanced very considerably beyond those times, and they must satisfy themselves that they were acting up to the spirit of the day in which they lived. He believed the desire of the Fruiterers' Company was to act on the same lines as those of the Royal Agricultural Society, and to promote, as far as their means would permit, the cultivation of fruit in our homesteads and agricultural cottage gardens throughout the kingdom.

It might be possible that in this way the Royal Agricultural Society and the Fruiterers' Company would be able to work together. The Fruiterers' Company would be glad to avail themselves to the fullest extent of the organisation of the Royal Agricultural Society. They encouraged agriculture in every district of the kingdom, and he believed it was the intention of the Fruiterers' Company to follow in their lines, and do what would promote the cultivation of fruit in all parts of the kingdom. He hoped as a Company they would be brought into very close relations with the Royal Agricultural Society. He was very glad that since a letter was issued to the public by the late Master—their very active and energetic Master, Mr. Mason—the subject had taken hold of the minds of the people of this country, and he believed there had never been a time when there was such a thirst for knowledge in regard to fruit-growing as there was at the present moment. They could not satisfy that knowledge, they could not give prizes, they could not encourage the cultivation of fruit unless they had the necessary means. He would like the public at large to place in their hands, say £10,000, so that with the interest of that sum they might, following the action of the Royal Agricultural Society, give encouragement to the various districts of the kingdom for the cultivation of such fruit as they had a capacity for growing, aye, and growing as well as any country in the world within their own borders. They were quite alive to the necessities of the position, and providing the public at large would come forward and support the Fruiterers' Company, they were willing to exercise their influence and the means at their disposal for promoting the cultivation of fruit in this country. Since the issue of Mr. Mason's letter they had received something like £1600, including £500 from the Fruiterers' Company, which, considering the small funds at their disposal, was a very large amount. One thousand six hundred pounds at the present time was all that was in the possession of the Company to enable them to carry out the scheme they had adopted. The subject was one of great national importance, and he hoped the public would assist them in their effort to restore the orchards throughout our homesteads and cottages, and add to the industries of fruit-growing.

Since they met twelve months ago a very excellent essay had been written for the company and published through the kindness of their friend, Mr. H. R. Williams. In that essay, which should be in the hands of every man in this country who had an acre of land, Mr. Wright had shown them how they might cultivate fruit at a profit, and he thought if the Fruiterers' Company had done nothing else during the year than produce that essay, it would be sufficient to justify their existence. He was inclined to think that the Legislature could do a great deal, and he thought that in all rate and State-supported schools in the rural districts the theory of horticulture, as well as the theory of agriculture, should be taught, and that these should be made compulsory subjects. What earthly good was it to a lad in an agricultural district who had to plough, and sow, and reap, and mow, that he should be taught something about science and art, and that no consideration whatever should be given to the very business in which he was likely to be engaged the whole of his

life? Technical education ought to be of a practical character, having reference to the districts in which it was given. So far as this subject was concerned, the Government of the day had risen to the situation, and in the Education Code which was put before Parliament last session, but which was unhappily withdrawn, Sir W. Hart Dyke provided that a Government grant should be given to all rate and State-supported schools for agricultural chemistry and the rudiments of agriculture, including horticulture, just as now grants were given in connection with the Science and Art Department of the Government. Whatever Government might be in power they would be impelled by the necessities of the nation to do what was required for the public good. Sir James referred to the great assistance which the Government of Denmark had rendered to agriculture and the butter industry, and asked why they could not take things up here in the same plucky and determined manner. By all means, he said, let them not forget that the greatest amount of wealth to this country came from our own soil. (Cheers.)

Major CRAIGIE regretted the absence of the chief of his department, Mr. Chaplin, and said that as the youngest member of the youngest institution of the State they would not expect him to say much. In representing very inadequately the missing link between the practical agriculture of this country and the Board of Agriculture he would only say that they watched with interest such movements as the one which had been initiated in the City of London, which must tend to the development of one of the most essential branches of the agriculture of this country. He pointed out that it had been already directed that in future the word "horticulture" should be included in the word agriculture. (Cheers.)

Colonel KINGSCOTE said he was sure it would be the wish of the Council and of every member of the Royal Agricultural Society to go hand and glove with this Company in promoting the growth of hardy fruit in every way possible. There was a great consumption of jam in this country, and they did not want any to come from a foreign source. If they put their shoulders to the wheel they could keep foreign countries out. There were hundreds of thousands of places in this country where the cultivation of fruit would be of the greatest advantage. Let landlords help future tenants by planting more trees, let tenants take more pains with the trees they had got, and let them be more careful in sending their fruit to market, and a glorious service would be rendered to the agricultural interests of the country. (Cheers.)

The LORD MAYOR said his father was the first man to introduce foreign fruit into this country, and in that capacity he had heard him spoken of as a public benefactor, for the introduction of foreign fruit had given employment and enjoyment to large numbers of people. His Lordship proceeded to refer to the great facilities afforded for bringing foreign Plums to England, and observed that the carriage was a very important item. His firm brought packages of Oranges in vessels they had chartered from Valentia to the wharf adjoining London Bridge. They weighed a hundred and a half, and were carried over in eight or ten days at 1s. 6d. freight. This was equivalent to four bushels of fruit. They must not shut their eyes to these facts. Let them make fruit-growing an item of education, but don't let them delude themselves, don't let them enter on a large enterprise and collect money unless they were assured there was to be some good result. His Lordship concluded by speaking of the energy, enterprise, and patriotism of the Master in very eulogistic terms.

The MASTER thanked the Lord Mayor for the kindly words he had said respecting himself personally, but he could not conceal the fact that he would have been more gratified if his Lordship had not damned the objects and aims of the Company with faint praise. He believed there was an opportunity of developing fruit-growing in this country, and he was sorry that on this matter he differed even to a slight extent from his successor. It was easy enough to say there were difficulties in the way. They recognised the difficulties, but did Englishmen ever give in because there were difficulties? He knew they could not grow Oranges in the open, he knew they could not produce Apricots and Peaches as they could be produced in the South of France and Spain, but he said they should in this country encourage the growth of such hardy fruits as they were capable of producing, and that they might in this way get additional production from the soil, which would go to increase the wealth of the nation. (Cheers.)

CATERPILLARS ON FRUIT TREES.

I AM perfectly convinced that very few people have the smallest idea of the dangers to which they are exposed in the growing of fruit from the ravages of the winter moth. There should, however, now be no more ignorance on the matter after the engraving given in your issue of the 30th of January (page 95). When it is considered that I have taken as many as 115 cuttings similarly infested from a tree not exceeding 7 feet high, your readers will understand how it is that the foliage and buds disappear with such rapidity when the warm weather hatches the eggs. "The prosaic work of pruning the trees again" was done here last spring, but in spite of that sufficient caterpillars hatched to leave the thousands of trees under my care quite bare of everything green. Further, the re-pruning furnishes the moths with fresh facilities to lay eggs during the autumn. What is wanted, in my opinion, is some substance to be applied to the ends of branches and covering up all nooks and crevices. If such can be done we can deal more easily with the eggs laid on the bark. I am making experiments with this view, and will let you know the results later on, and also, should you wish it, send duplicate specimens. Our

Pear trees were so weakened last year by the caterpillars that our crop this year will be nil.—S. T. WRIGHT, *Gleuston Court Gardens*.

[We shall be glad to hear of the results of the contemplated experiments with such specimens as our correspondent thinks may be usefully sent. The best efforts of the best men in growing fruit may be completely nullified where the destructive winter moth abounds, and every effort should be made to conquer this the most ruinous of the fruit growers' enemies. The idea of sealing the ends of branches after pruning occurred to us, but we felt certain it would also occur to our correspondent, and we preferred that he should have the credit of the suggestion.]

GARDENERS OUT OF SITUATIONS.

YOUR correspondent, "B.," page 60, has made some remarks on the above subject, and throws out some hints as to the formation of a self-help society, and which is possibly a direction in which some good might be done, but "so many out of place" has been the cry in my experience for nearly forty years, and of course a pleasant healthy trade or calling like gardening will always attract more than can possibly find good places in Great Britain, and the consequence must be that numbers on reaching man's estate must change their occupation or emigrate with a knowledge of the cultivation of the soil. It has been said that London itself is under the care of a certain number of under gardeners in uniform; meaning that the London police are largely recruited from our ranks, and of which I, for one, do not feel at all ashamed. Your correspondent says, What does a gardener gain by working for a nurseryman when out of a regular situation? I say a great deal, provided he keeps his eyes open, and employment mentally and physically is good. It is well known that in such cases their pay is small, but a man would not show his wisdom by refusing half a loaf if he had no bread. "B." further says he gains nothing for himself, and does a great injury to the permanent staff of a nursery; to my mind a ridiculous assertion. The gardener is quite the equal of the best kind of men employed in nurseries, and if the gardener is worthy of his salt, although receiving small pay in a nursery, he will do a fair day's work in an upright manner. No doubt there are black sheep in all walks of life, but these must not be classed with the general body. I maintain that the connection between nurserymen and gardeners, both in and out of situations, is a perfectly just and honourable one to all, the best way of getting the right man in the right place. What would be the use of nurserymen keeping qualified men to produce good nursery stock if they knew their clients had not qualified gardeners to make the best of it? In such cases the reputation of the nurserymen is often in the gardener's keeping, and both can work together in an honourable way without loss of dignity on either side.—R. M.

IN answer to "B.'s" views in page 60 in this paper of January 23rd respecting a society being formed in aid of gardeners out of situations, I quite agree with the suggestion. For years past my views have been the same as "B.'s" on that subject, and I have often discussed the matter with many of my brother gardeners, who have also agreed on the above. I for one would be glad to become a subscriber, and would endeavour to do my best among my brother gardeners, friends, &c., in this district to subscribe to the above should such a society be formed, which I believe would be a success.

I think if most of our kindhearted brother gardeners were to unite together throughout the country, and subscribe so much annually to form a society in aid of gardeners out of employ, this would be a great boon and relief, long looked for.—GARDENER, *Surrey*.

THE letters of "B." and "H. B. W.," page 93, are worthy, I think, of serious thought and attention by our leading men. I am of the same opinion as your correspondents, that it is time gardeners combined together more for their own interests. Surely many would be willing to join such a society for helping those who are out, very frequently not their own fault. I shall certainly, for one, whenever I am in a settled place, be willing to do my part towards the object. Could not something be done by the Committee of the United Horticultural Provident Society? I throw out the hint for what it is worth, and hope the members will be able to take up the matter. Let me urge upon all young gardeners to join this Society, they will find it answer better than any other provident society I know.—A. B.

THE PARSLEY-LEAVED BRAMBLE.

YOUR correspondent "Rubus," on page 61, appears to have been at some pains to discover the native home of this, which is, I believe, the best and most useful amongst the large-fruited Brambles. Mr. F. Boyes, on page 48, is quite correct, I believe, in his assumption that it originated in the nurseries of Messrs. Fisher, Son, & Sibray—then Fisher, Holmes & Co. The principals of that firm have repeatedly informed me verbally, and they have also published the same on a leaflet which they distributed to their customers many years ago, that it originated as a chance seedling—probably from the American variety "Kittatinny"—in their nursery grounds some thirty or more years since.

Mr. Udale, I think, strikes a right chord in his remarks as to its requiring a good warm sunny position to ripen the long and strong canes made annually in order to obtain the most fruitful results. The

row which has been several times alluded to as being under my cultivation for some years at Oakbrook, occupied a similar position on a south border to what that did at Elford Gardens, which I have several times had an opportunity of seeing, and of observing that they were equally as fine in growth, and as fruitful, as were those at Oakbrook. I think the mistake is too often made in its attempted culture that being only a mere Bramble any out-of-the-way corner was sufficiently good for it. Such is not the case, as Mr. Udale points out, and given such results in fruit production as achieved in the several cases he cites, it will well repay the cultivator for giving it one of the best positions at his disposal.—W. K. W.

[We shall be glad to know the year in which the seedling appeared at Handsworth.]

EUCHARIS AND THE MITE.

MR. TAYLOR's experience in destroying the Eucharis mite on the affected plants in his charge is interesting as affording another instance in which the dreaded enemy has been "bearded in his den," and the rapidity with which the plants have grown since is conclusive proof that the conditions for their growth could not have been very unfavourable. Three partially decayed bulbs filling a 10-inch pot within a year is no bad record; but Mr. Taylor has only followed the lead of the correspondents to whom he refers by detailing his experiences, for surely there is no better way to help another through a difficulty than by relating the manner in which that difficulty has been overcome by oneself, although I fail to see why he should give precedence to the experiences of an amateur or beginner. Mr. Taylor says he has proved three things, and the third affords room for an epithet to be applied to any gardener who may have unhealthy plants in his charge, which could not have been applied with the same force after the remarks of any writer who assigned the cause of their unhealthy state to mismanagement, besides being rather contradictory to the sentence in which he says something about calling our brother gardeners unskilful. No gardener worthy of the name would intentionally say or write anything which might get a fellow craftsman into trouble, and if in any instance this has been done we may be sure that the shaft found mark "the archer little meant." It would have been better had Mr. Taylor proved fourthly how the mite originated before he slighted the claims already advanced. Does he believe in spontaneous generation?—M. D.

TOO SUCCESSFUL PRIZEWINNERS.

WHILE I do not approve of "Head Gardener's" proposal of withholding all first prizes above three guineas by one competitor, I have been long of the opinion that instead of dividing, say £10, into three prizes, £7 for the first, £2 for the second, and £1 for the third, it would give more satisfaction to the general public if first, second, and third prizes were named only in the prize schedule, leaving the amount to be divided by the judges to the exhibits according to merit. Frequently the competition is very keen or close, the judges having a difficulty to decide the honours; then sometimes the second and the third best are very deficient and below the standard as prizetakers, having little or no merit whatever to entitle them to a prize. Some managers of local shows encourage competitors by paying prizes, although the exhibits do not deserve it; but I consider at country or open competitions the judges should have, in addition to awarding the prizes, the power of fixing or dividing the amount according to merit. I have always thought it disheartening to a competitor to be content with almost nothing more than the name as a second place prizetaker, while the first one had little in the exhibits to recommend it over that placed in an inferior position, while both had the same labour and expense in bringing their exhibits before the public.

Say for Roses, A takes first prize, B second, and C third. The exhibits were so near each other in competition that the judges awarded the £10 offered in the following order:—A, £3 10s.; B and C, £3 5s. each. I am of the opinion some system such as that would be fairer than the present one, while it would be encouraging, and more competition would result.—WM. THOMSON.

AS you invite suggestions to meet the letter of "Head Gardener" on this subject, printed in your answers to correspondents on page 79, I should like to say that I think most persons will heartily agree with your editorial recommendations. It depends a good deal upon whether "a too successful prizewinner" competes on precisely equal terms with the other cottagers. If he does, there is no remedy for them but to pluck up a little spirit, and try to beat him. Let them learn from him, and if necessary try to win in detail by becoming specialists, one going in particularly for Onions, another for Potatoes, and so on. But although there certainly is a terrible want of pluck in cottagers as exhibitors of garden produce, the Committee must remember to "be just before it is generous," and should not rob a man of a first prize to which he is fairly entitled.

But if the "too successful prizewinner" is or has been employed in any garden it will be suspected, even if it is not true, that he does not compete on perfectly level terms, and in my own cottage flower shows I have been obliged to make a separate division for persons of that class. Such a one often shows his superiority, not so much by his being able to get better seeds, &c., as by his better knowledge of what is a good vegetable and what is a bad one. Here, again, the other exhibitors

might learn in time to beat him simply by a study of the first prize exhibits as compared with their own; but, as I have said, they have no enterprise for this, soon get disheartened, and give it up altogether. Every effort should be made to teach them the good points of the different exhibits—a little speech or lecture, or something of this sort, on the day of the show, when the vegetables, &c., are there before them, will probably be found useful to this end.

Two or three years ago the local show of a neighbouring village gave a prize for the "biggest" Potato! (Oh, Paul Neron, H.P.! what a time you would have had if the N.R.S. medals had been given for biggest Roses!) so I issued a counterblast by offering two prizes for "the best (not biggest) round and kidney Potatoes" in our show. The winning tubers were prominently displayed with their cards attached to them, and the cottagers were exhorted to take them as samples for selection.

They have learned, I believe. We had last year fewer specimens shown which were "White Elephants" by nature as well as by name, and I shall not be surprised if the cottagers are well up to the gardeners in the matter of Potatoes on the next occasion.—W. R. RAILLEM.

HAVING a similar difficulty to contend with in our local show as that stated by "Head Gardener," the following rule, irrespective of class, was inserted in the schedules, "No exhibitor to take more than six prizes." Exhibitors knowing beforehand the number of prizes allowed entered accordingly. Following the above rule gave general satisfaction, and a more equal distribution of honours.—T. H. SLADE.

FRUIT FORCING.

FIGS.—Earliest Trees in Pots.—The trees started in November for affording ripe Figs early in May will be forming fresh roots plentifully, the bottom heat being kept steady at about 70° to 75°. Raise the fermenting material to the rims of the pots, and instead of allowing the roots to come over them to ramble unchecked in the fermenting material, place pieces of good turf round the rims to keep the roots near home and to induce sturdier growth. Maintain genial moisture in the atmosphere by syringing twice a day and damping as may be required in bright weather. Admit a little air at 70°, increasing it with the temperature; close at 75°, and if the temperature rise to 80° or 85° from sun heat it will be an advantage. See that there is no lack of water at the roots. The drainage being good there is little danger of giving Figs too much water, many crops being lost by the soil being kept too dry. The temperature in dull weather must be kept at 60° to 65°, 55° to 60° at night when the external air is cold, but 5° higher when the weather is mild. Disbudding will need attention as growth advances and gross shoots are stopped, but the finest Figs are borne upon extensions.

Early Forced Planted Out Trees.—The trees planted in inside borders and started early in the year are commencing growth, and may have the night temperature raised to 55°, 60° to 65° by day from fire heat, with an advance from sun heat and free ventilation to 70°, or even 75°. Syringe twice a day, and see that the borders are thoroughly moistened. If the trees are weak a soaking with liquid manure, not too strong, at a temperature of 85° to 90° will assist the growth.

VINES.—Eyes and Cut-backs.—Eyes may now be inserted, using pots, pans, or square pieces of turf. Select firm well-ripened wood, filling the pot or pan with rich friable loam; insert the buds with a pinch of silver sand, and half an inch beneath the surface plunge the pots, &c., in a bottom heat of 80°. Cut-backs should be placed in a house where they will have a temperature of 60° to 65° at night, and 70° to 75° by day. When they have started into growth shake them out and return to the same size of pot, using good friable loam, and give a rather close and moist atmosphere until re-established, when they should have a position near to the glass, so as to insure sturdy, short-jointed, thoroughly solidified growth.

PINES.—Fruiting Plants and Starters.—These are showing fruit, and should have a mean temperature of 70°, varying 5° according to the weather, admitting air at 80° with sunshine, but do not lower the temperature. Allow it to rise to 85°; close between that and 80°, and if it rise somewhat after closing it will be advantageous rather than otherwise. The plants recently started into fruit will, if in good condition at the roots, produce strong suckers. When the suckers are large enough to handle, all except one to each plant must have the growth checked by taking out the centre. To supplement the autumn potted plants select others which have been wintered in 7 or 8-inch pots, choosing the most vigorous. Those remaining may be reserved until the general spring potting, when they may be shaken out and treated similarly to suckers. Good fibrous loam, with the turf well reduced, placed under cover to become dried, is a suitable compost. Drain the pots well, dust dry soot or wood ashes over the crocks to exclude worms, and ram the soil firmly round the plants, keeping them well down in the pots to admit of copious supplies of water being given when necessary; 10-inch pots are suitable for Queens, and 11 or 12-inch for

those of more robust growth. A temperature of 60° to 65° will be sufficient for these plants, also those potted last autumn, and about 85° bottom heat. Plants in beds about to be started into fruit must not have the heat at the base of the pots over 90° or 95°, or their roots will be injured. If sufficient fruits be started to meet the requirements later successional plants that have not been subjected to a high temperature may be advanced slowly, they with autumn-rooted suckers requiring careful watering, especially where the heat at the roots is supplied by fermenting materials.

STRAWBERRIES IN POTS.—When the plants commence flowering admit air freely, remove the weaker flowers, and when the pollen is ripe brush the flower lightly with a feather. After the fruit is set, thin them to about half a dozen to each plant, more or less according to the variety. Whilst the fruit is setting 50° to 55° will be sufficient heat artificially, advancing to 60° to 65° with sun heat, but after the setting is effected remove the plants to a house with a temperature of 60° to 65° artificially and 70° to 75° by day, supplying liquid manure until ripening commences, then employ water only and sparingly. Whilst swelling they require a moist genial condition of the atmosphere.

Successional plants must not lack water, but needless watering is highly prejudicial, therefore examine each plant and afford a supply only when needed. The plants must not be brought on too rapidly in the early stages, a temperature of 50° artificially is ample. If there be any trace of apbides fumigate moderately, taking care to have the plants perfectly clean before they cease flowering.

HINTS FOR BEGINNERS.

FEEDERS AND FEEDING.

SYRUP suitable for feeding bees is made by dissolving sugar in about its equal weight of water. When syrup is too thick the bees cannot use it. If the beginner is anxious to feed from a large surface for rapid feeding, let him procure a solid piece of yellow pine the width wanted, and an inch or so narrower than the top of hive from front to back, and about three-eighths of an inch thick. Now prepare and joint at the corners pieces about an inch broad by half an inch thick, and nail this firmly to the sole. One of the pieces is kept three-eighths of an inch lower than the others, which has a groove three-eighths from the top to the bottom to receive a pane of glass. As a resting place of wood is required in the centre for the fountain, two panes of glass become necessary.

The hole to receive the neck of the fountain must be bridged in to prevent bees escaping. The bottom of feeder is filled in with strips of wood a quarter of an inch square, having little pieces an inch long or so, to keep them apart a quarter of an inch. This gives the bees a quarter to rest upon and a quarter to sip the syrup. These short pieces must be three-eighths of an inch deep, so as to leave one-eighth beneath to allow syrup to flow, and prevent bees getting under, as they do when floats are used in deep feeders. I see I have omitted to state that an inner rim should be nailed firmly to the sole three-eighths high. This forms the feeder proper, while the outer one prevents the bees escaping, and admits the glass coverings and space for bees. While this has the advantages of a rapid feeder, the bees are within three-quarters of an inch of the syrup, but is not to be compared to the universal feeder previously explained.

There should be a feeder for every hive, and these, as well as the hives, numbered when types are not at hand. A thin punch about three-eighths broad does well to mark Roman figures on zinc, the raised side being kept uppermost and fixed permanently to the hive and its appliances.

STORING APPLIANCES.

Unless the beginner adopts some method of keeping things in their proper places, and to know where these places are, he will soon get bothered. Whether appliances are kept in presses or boxes, trays should be largely in use. A general index should be fastened to each press or box, or in a book, and each tray should have a note fastened externally, describing each article it contains. Four pieced sections come in handy for little boxes to hold nails, seeds, &c., and I find where seeds have not been thoroughly dried at

harvesting, when kept in tin their vitality is sometimes destroyed, while those kept in wood are good.—A LANARKSHIRE BEE-KEEPER.

THE HONEY PRESSER.

BEING in Glasgow on Friday last I met with a number of gentlemen (readers of the *Journal of Horticulture*) who, disapproving of some other journals in refusing to correct errors, requested me to draw your attention to the following case:—

Notwithstanding the number of public refutations respecting the origin and construction of the honey presser the following appeared in the "British Bee Journal" on January 16th in answer to a query:—"Unless Heather honey is extracted from the comb just before it is sealed it will in anything like a good season be found to set so firm as to render extracting impossible. The late Wm. Raitt invented the honey press to meet the difficulty.—ED."

No less than twelve different persons called my attention to the error, advising me to refute the same by stating facts. One of these letters was from a gentleman who was a judge at the Caledonian Society along with Mr. Raitt, but who adjudicated in different classes. Appended is my reply to the journal in question.

SIR,—My attention has been drawn to an erroneous statement in the "British Bee Journal, &c.," page 36, where it says that "the late Wm. Raitt invented the honey presser." Mr. Raitt did not invent that implement. It has been in use in this country for at least half a century, and up till 1885 or 1886 that gentleman squeezed the Heather honey through his hands. This information in presence of many witnesses I had from his own lips at the Centenary Exhibition of the Highland and Agricultural Society, held at Edinburgh in 1884, where he adjudicated on an exhibit of mine, and had the great pleasure of rejecting it as not being an extractor conforming to the schedule of the Society, an opinion shared by no competent person present. The instructions attached to the implement were faithfully copied, and subsequently appeared in the pages of the "B. K. R." as a help to anyone who would undertake the manufacture; what is now termed the "Raitt Honey Presser," being neither more nor less than a slight modification of the first principles only of the Lanarkshire one. I have always considered that information should be well mingled with truth, and for that reason, perhaps, you will allow space for the refutation of the error.—WM. THOMSON.

The following is the Editor's reply:—"Rait Honey Press.—In last week's issue we spoke of the honey press as being 'invented by the late Wm. Raitt.' Mr. Wm. Thomson of Auchinraith, Blantyre, informs us that he is the inventor of the principle of the honey press, also that he exhibited the press at Edinburgh in 1884. We offer our apologies."

Your readers will readily observe the wide difference between my letter and the apologies. Such a letter, by J. D. McNally, appeared in the "Bee-keeper's Record" some time since, and when laid before a meeting of the Caledonian Society every word was disproved, and the letter characterised "as vile as it was untruthful."

For the benefit of all concerned I will give the facts about the honey pressers as well as their uses and construction, but before doing so may explain that Heather honey, although unsealed, will not yield to any extractor. It sets to an immovable thickness within a few hours after being gathered by the bees.

So far as my own knowledge is concerned I cannot go much further back than fifty years. At that time honey pressers were in use, but were mostly similar to those used for cheese pressing. Nearly forty years ago I had a presser with screw and rack combined. This one, as well as all others I saw, were too wide, much honey remaining amongst the combs, and all too slow in action.

Several persons in Lanarkshire about the same time conceived the idea of a perforated tube or bottomless cylinder, which wrought satisfactorily in pressing the honey from the combs, but the perforations were too large, and it took three to work it satisfactorily—one to cut the combs and fill the tube, while a second rammed it, and the third turned the screw, as it is unpleasant to do this with honey-smearing hands. Then there was another disagreeable move, that of lifting the tin tray to allow the comb to be pressed out. At this point I came upon the scene with improvements, substituting small instead of wide perforations, and a slide which by four movements a person can press the honey and the other work, instead of three as formerly, and this without putting a finger upon the honey. I also put a platform on the cylinder, so that the screw holds it rigid while the combs are being rammed. There are other minor things in connection with it, but which require to be seen to be understood rightly.

The presser is of polished metal, and is useful for other things besides forcing honey from the comb, such as pressing fruit, the juice from herbs, &c., also for crushing melted combs to extract the wax. I also use it for fixing foundations to sections;

for this purpose two pieces of wood are required, and a sole with two kneed pieces of iron, having a hole near the top to receive the ends of a wire crossing on the under side of the upper piece so as to be balanced. The ends of this upper piece are of different sizes to suit two sizes of sections, and have a piece with a tooth formed on front edge to press the foundation one-eighth broad. On the sole there is a thin piece of wood with slots to suit any breadth of section, and on this lies a tongue of tin close to the tooth of the upper jaw to keep the foundation in its place. The operator has only to sit in front of the press and push the section with foundation forward and give the screw a half turn, then fold up the foundation to face of guide. As will be observed, the upper piece being balanced a small article such as a penny placed upon the back part raises the front portion hard to bottom of the screw, which makes the work easy and perfect. This mode of fastening foundations, although termed American, is in reality German, the instructions being obtained through Mr. Alfred Neighbour in 1862.

Some years since I promised to do my best to bring, through the help of an engineer, a suitable cheap presser for bee-keepers, but unfortunately he went out of business shortly thereafter. I have, however, again consulted with a person who has promised to manufacture one as a trial from my patterns, but fear when all the necessary improvements are added the price cannot be less than from 40s. to 50s., but even at that it is a cheap and useful implement no bee-keeper having Heather honey should be without. Many people have been prevented having one through incompetent judges rejecting useful implements, and awarding prizes to useless articles, as was done at a certain show to a presser in imitation of the Lanarkshire one, having by far too weak a screw, and the tube with a bottom, from which the wax could not be taken by any means short of boiling, the Judge in this case believing the statement of the owner that the wax or pressed comb would drop on being inverted!—A LANARKSHIRE BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

Vilmorin, Andrieux & Co., 4, Quai de la Mégisserie, Paris.—*Catalogue of Seeds.*

Kelway & Son, Langport, Somerset.—*Plant Manual for 1890.*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Fumigating (C. Dublin).—Your letter is distinctly an advertisement, though perhaps this did not occur to you when writing, and its character is not altered by your having no pecuniary interest in the sale of the article recommended. A genuine article is always worth advertising.

Pea Hurdles (W. L.).—These are used when good sticks cannot be obtainable except from long distances, which of necessity increases their cost, and their speedy decay renders them expensive. Moreover, some owners of gardens prefer the hurdles because of their neat appearance. They were "written about" in our columns a few years ago, and gardeners who have used them are at liberty to write about them again with the object of giving information, and if their communications are suitable they will be inserted. Some persons are satisfied with a row of hurdles on one side of the Peas, running a few lengths of string along the other, and looping them across to the hurdles; others have the hurdles on both side the rows. It is a question of taste or outlay.

Bitter Seakale (M. C. B.).—When Seakale produces strong crowns, the result of thinning the growths in spring and rich soil, and the blanching material is perfectly sweet; or if the roots are taken up and the growth forced in a dark, sweet, warm house, we have not found the produce bitter when properly cooked; but if the growth is not made in total darkness and sweet surroundings, then the Kale is more or less

unpleasant when served, as it is when permitted to remain long after being cut in a dry place before being cooked. Perhaps the plants in your beds are crowded, and it might be prudent to establish some young plants for producing stronger crowns, not, however, destroying the old prematurely. Sets with bud growths now or incipient crowns planted 18 inches asunder in deep rich soil, and the ground hoed frequently, produce fine crowns by the autumn, but if crowded together in poor dry soil only weak crowns can be expected.

Heating Cucumber House (C. J. H.).—The piping you propose for furnishing top heat—viz., two 4-inch pipes, is not enough, as to maintain a suitable temperature the pipes will require to be highly heated, and heat radiated at a high temperature is not good for the foliage of the Cucumbers. We should advise an extra pipe, or preferably two, whereby you will attain to more satisfactory results both as regards the Cucumbers and economy in heating. Two rows of 4-inch pipes will be sufficient for bottom heat, and we should have them in a chamber not more than a foot deep, and covered with slates, so as to form the bottom of the bed, which should be kept just clear of the hot-water pipes. If you use rubble it should be brought over the pipes to the extent of 6 inches, and it must be covered with a layer of turves to prevent the finer particles of soil passing into it. Both are good plans, but we prefer the chamber. The boiler will certainly be sufficiently powerful for heating the piping you name, also for the additional piping we strongly advise your employing for cultural and economic considerations.

Variation in Pears (J. S. W.).—Your experience is interesting. The two fruits were not only quite dissimilar in shape, eye, stalk insertion (though in this respect one was imperfect), but in texture of the flesh and flavour; yet "they both came from one tree." If a graft or bud has not been inserted at some time the difference must be attributable to "sporting." Similar instances are not unknown, though they are not common. That a Pear tree will occasionally "throw" one or more fruits totally different from the general crop has long been recognised by pomologists, and in some instances the sports have exactly resembled the fruit of another well known variety. The change has been attributed to the influence of pollen, in which the characters of varieties are conveyed, but not always retained unmixed in the tree to which the pollen is transferred. It is singular that the fruit should thus be changed, but it is so, though examples are rare, or are not sufficiently marked to command attention. In such instances as yours the foliage would not be changed, but the seeds probably would, and it does not follow that the same phenomenon will occur another year; if it does we shall be obliged by your sending us more fruits from the sportive tree.

Golden Russet Apple (E. L. B.).—You have been correctly informed in this being a good dessert Apple. It is, in the estimation of many good judges, one of the best, but the tree is not one of the most hardy, and sometimes assumes a stunted habit when trees on the Paradise stock are permitted to overlaid themselves in a young state. The following is the "Fruit Manual" description of the variety with the author's note appended:—"Fruit, medium-sized, 2½ inches wide, and 2½ inches high; ovate. Skin, thick, covered with dingy yellow russet, which is rough, thick, and scaly on the shaded side and round the base, and sometimes with a bright flame of varnished red on the side next the sun. Eye, small and closed, or half open, with erect convergent segments, set in a prominently plaited basin. Stamens, median; tube, conical. Stalk, very short, inserted in an uneven cavity, and not protruding beyond the base. Flesh, pale yellow, firm, crisp, sugary, and aromatic, but not abounding in juice. Cells, obovate; axile, closed. An excellent dessert Apple of first-rate quality; in use from December to March. The tree is healthy and an excellent bearer, but requires a warm situation to bring the fruit to perfection. This is another of our old English Apples. Worlidge calls it the Aromatic, or Golden Russeting, 'it hath no compeer, it being of a gold-colour coat, under a russet hair, with some warts on it. It lies over the winter, and is, without dispute, the most pleasant Apple that grows, having a most pleasant aromatic hautgust, and melting in the mouth.' It is called St. Leonard's Nonpareil about Horsham from being grown under that name at Leonard's Lee, near that town."

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (W. H. W.).—As far as we can judge from the out-of-condition specimens, the Apple is the Golden Russet. See reply to a correspondent on the subject.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (J. W.).—It is one of the numerous hybrids now introduced in almost every consignment. It is pretty, but it is impossible to give names to all the forms, and it is probable that some rather restrictive rules will shortly be adopted with regard to this matter. (J. E.).—1, Camellia Waratah; 2, Camellia altheaeflora.

COW AND DAIRY IN WINTER.

ALTHOUGH these articles embrace all kinds of farming, yet they are specially intended to assist the managers of home farms, both large and small. That such aid is required and valued we have ample evidence, and quite recently a case very much in point came under our notice, some particulars of which may be useful to any of our readers in a similar situation.

It was a small place, where the head gardener had entire charge of the garden, land, and live stock, which consisted of three or four cows, a few store beasts, and some pigs and poultry. The land was heavy, and so retentive of moisture that no system of drainage could relieve it of surface water quickly without a total change in its mechanical condition. In such a wet month as January was the surface of the land was sodden with moisture, and decidedly unfit for animals of any kind to be turned out upon it, yet upon

every fine day the cattle were turned out, simply because it seemed better for them than standing in a small enclosure in several inches of mud, for there was no litter used, as all the land was in pasture, and what straw is used must be purchased; there was therefore much exposure of the animals to cold and wet, with the result of two cases of abortion—one by a cow, highly valued for its deep milking properties, the other a promising heifer; a serious matter in any case, but especially so in such a small herd.

Our inspection enabled us to point out certain faults of arrangement and the remedies. The cowshed was so small and badly ventilated as to be quite unsuitable for its purpose. The remedy is a commodious cowhouse with weather-proof walls and roof, roof ventilation, floors of 3-inch Portland cement with a wide gutter and drain, and large separate stalls for each cow. The cows to be kept in and stall fed all the winter, the use of litter to be optional, but thorough cleanliness of floors, divisions, and walls to be strictly observed. A loose box and calf pen to be built outside the cowhouse for down-calving cows, entrance to the loose box only by an outer door, to ensure entire separation from the other cows in any subsequent cases of abortion. A cowyard with an open lodge to be added in due course, but as the locality is so cold and wet, close housing of cows always to be followed in winter. It was also advised that as there was an undue area of pasture for grazing and hay, enough should be broken up for the growth of forage and grain, and that the number of store or fat cattle on the farm should always be subservient to dairy requirements. It did not appear advisable to procure horses and implements for the arable land, which would only extend to a few acres, and could easily and economically be done by neighbouring farmers. No attempt will be made to prepare it for spring corn this year, but it will have the surface pared and burnt when the weather becomes favourable, and then be got ready for next season.

When cows are kept in altogether in winter they should always have a moderate quantity of Cabbages, Carrots, and Mangolds mixed with their food, of which the bulk should consist of the best meadow hay, the coats should be dressed daily with currycomb and brush, and the udders washed before the milking. Much more attention is now paid to cleanliness and comfort in the cowhouse than formerly, in view of the promotion of health, of a well sustained yield of milk, of cleanliness and purity in the milk, and of improvement in the quantity and quality of the butter. The greatest advance in this improvement of practice appears to have been made in Denmark by the Copenhagen Milk Supply Company, which disposes of some 18 tons of milk daily, supplied by farmers whose cows are specially selected and regularly inspected by a veterinary surgeon. The most rigid cleanliness is observed, as well as fixed rules for the dictary, which in summer consists of grass and Clover, and in winter of hay, straw, Oats, Barley, and Carrots; a most wholesome mixture that is quite certain to impart no taint to the milk. But the novel feature consists in a system of filtration through compressed sponges as the milk is delivered, and it is said that notwithstanding all the care taken at the farms to have clean hands, clean udders, clean utensils, the quantity of foreign matter taken up by the sponges from the milk is extraordinary. If this is so, the introduction of the milk filtration into this country is only a matter of time, and till then really pure milk seems out of the question. For persistent effort and thorough painstaking with both milk and butter the Danes are so far unrivalled. They have now a continuous butter show for several months of the year, at which exhibitors have to send fresh samples at intervals of fourteen days, and at other times as the judges may require.

WORK ON THE HOME FARM.

Advantage has been taken of the unsettled weather to procure and mix chemical manures for pasture, the proper quantity per acre being weighed from the mixed heap, and put aside in bags in a dry store house till required for use. With the moderate quantity of soda we use, mixing two or three weeks before use may be done without risk of harm; but when an excessive proportion of superphosphate is used the acid acts so strongly upon soda and potash that if the mixture is not used quickly it

becomes a damp sticky mass, most difficult to use at all. This is a serious matter in any case, but more especially when a large quantity is mixed.

We have some very large barns, which are usually filled with corn sheaves at harvest time. Especial care is taken that all of this barn corn is in thorough good order when carted in from the fields, in order that it may be threshed sufficiently early to render the barns available for other purposes. A barnhead is a capital place for storing chaff, and we have just cut up enough Oat and Barley straw into chaff to last till turn-out time comes, be the spring early or late. We like a little heat in such chaff heaps—it imparts flavour, and renders the chaff more palatable than it would otherwise be. The beating is induced by sprinkling a little common salt among the chaff as it is put into the barn, and by a moderate trampling of each layer. This matter is now out of hand, and there will be an ample provision of horse food during seed time, when a stoppage for chaff cutting would prove a serious matter.

Grass may positively be said to have continued growing throughout this mild winter, and there has been a much less demand than usual for trough food for sheep; but it has been a trying winter for flocks suffering from foot rot, and more care than usual has been necessary to keep this insidious disease down. So far autumn-sown crop look a strong full plant, but there is much risk of early sown Tares losing plant now, and a close watch must be kept, in order that any failures may be made good by early sowings of spring Tares. It is some seven or eight years since we lost the whole of our winter Tares in a mild wet winter, and the loss proved so serious a matter that in order to avoid the risk we have always since then kept back the sowing till well into October.

OUR LETTER BOX.

Manure for Clover (K. J. A.).—As the Clover is a full plant the land is evidently not Clover sick, but the plant being small and weak shows poverty of soil, for which the proposed dressing of gypsum would certainly not prove an effectual remedy. The prescription given for pasture a fortnight ago would answer perfectly well for it, if only you are careful to keep strictly to the formula, to procure each sort of manure separately from a reliable source and superintend the mixing yourself. We fear you have not done this hitherto, for the failure you mention in 1888 tends to show that you could not have used genuine manures or not applied them at the right time. We have used the mixtures we have so often recommended on light, mixed, and heavy land with singularly uniform success, and are positive that your failure was not owing to the formula. In so wet a summer as that of 1888 good artificial manure was more than usually effective. We used about £400 worth that year at six different farms with excellent results, but then we used pure manures in the right way. Be assured that we never recommend any manures we have not proved to be good, and do not allow anyone to induce you to substitute other manures for those we mention, or you may thus court failure. For example, we recommend muriate of potash, which contains when pure 52 per cent. of potash, often more. Instead of acting upon our advice you allow yourself to be persuaded to substitute sulphate of potash, containing only 44° of potash, and often a great deal less, for it, and then complain of the result. We may remind you that the most economical way of restoring the vigour of your Clover layer is to fold sheep upon the first growth, and then you have the option of turning the second growth (which is certain to be vigorous) to account either for seed or forage. But if you require a vigorous first crop then by all means use the chemical manures, and in doing so on your light sandy soil you ought to be especially careful to use it early, so as to insure that it is dissolved and washed into the soil by the time active growth begins. Last year was an exceptionally favourable one for light land, and had you drilled in chemical manure with the Barley you would not now be complaining of a weak Clover plant.

REMARKS.

26th.—Bright morning; cloudy afternoon; showery evening; frequent heavy squalls of wind all day.
27th.—Showers early; bright from 10 A.M. till night.
28th.—Very wet from 1.0 A.M. to 11 A.M.; fine with a little sun at mid-day; showery and drizzly afternoon and evening.
29th.—Almost cloudless throughout; solar halo at 3 P.M.
30th.—Fine and occasional sunshine; spots of rain in the evening.
31st.—Dull and drizzly all day.
1st.—Slight fog till 10 A.M., then overcast.
Another warm week, with a considerable rainfall, but much bright sunshine.—
G. J. SIMONS.

AN interesting feature of the meeting of the Royal Horticultural Society on Tuesday last was the proposal of a plan announced by Baron H. Schröder for raising the necessary funds for the acquirement of land and the erection of a building that would not only afford the requisite conveniences for the transaction of the business of the Royal Horticultural Society, but for other societies, including those of a benevolent nature connected with horticulture. The proposal of the Baron is to acquire a fund of £40,000 to be invested in trustees, the interest from the investment of which is to be devoted to meet the demands for ground rent; and a portion of the principal to the erection of a building. The invested sum is to be repaid to the contributors without interest by the annual redemption of bonds.

When a gentleman of the wealth, position, and influence of Baron Schröder initiates a movement of this nature, that fact of itself must inspire confidence, and induce many who are in a position to do so to co-operate with him in carrying it on. There are many persons of wealth who are deeply interested in horticulture who may be expected to willingly invest in the fund to be created for such a purpose when they see that it is being established on a substantial basis.

The Baron's proposal met with a warm reception, and in the course of a few minutes, after the meeting was over, and many gentlemen had left the Council room, spontaneous offerings amounting to £2600 were made towards the object in question. We have obtained the names of some of the gentlemen, with the amounts of their promised contributions:—Baron Schröder offers £1000, Messrs. F. Sander & Co. £200, Messrs. S. Courtauld, N. N. Sherwood, and H. J. Veitch, each £150; Messrs. P. Crowley, T. B. Haywood, Dr. Hogg, C. Mordaunt Matthews, and H. M. Pollett, each £100; Messrs. G. Deal, John Laing & Sons, G. Paul, H. J. Pearson, T. F. Rivers, and Rev. W. Wilks, £50 each; Miss J. Douglas, H. Cannell & Sons, Mr. John Treble, and Messrs. Sullivan, £25 each; Mr. George Bunyard and Mr. Charles Toope 10 guineas, and Mr. Cecil H. Hooper £5. This is evidence of earnestness, and the best beginning that has yet been made by horticulturists towards providing a suitable central establishment in the metropolis that will adequately represent the great and growing art and industry with which they are connected.

Obviously those names only represent a fringe of the horticulturists of the kingdom, and it is hoped the contributions attached to them are a foreshadowing of the realisation of the much-needed and desirable undertaking. The moment seems favourable for the prosecution of an enterprise of this nature. Commerce is expanding, trade is extending, and the Fellows of the Royal Horticultural Society increasing. The great garden-loving community, moreover, is satisfied that the Royal Horticultural Society is pursuing its legitimate functions, and the feeling is practically unanimous that the present London office and hall are wholly inadequate for the purposes of the Society. They were obtained as the best procurable for affording temporary accommodation, and always in the hope that premises of a more suitable nature would be in due time provided. Baron Schröder's proposal appears the most practical that has yet been submitted. It is made at an opportune time, and has been hailed with an unanimity of satisfaction that commends it to the most favour-

able consideration of horticulturists, amateur and professional over the length and breadth of the land; it has the merit also of not imposing on the Royal Horticultural Society any fresh liabilities. It is not promoted by the Society, but for it and under its auspices; and not for it alone, but for allied Societies and all appropriate objects, not the least being those of a benevolent, charitable and prudential character, as represented by existing institutions, which at present are without a recognised home and habitation. Baron Schröder's broad and business-like proposal is commended to the favourable consideration of all who are in sympathy with the object in view.

METHODS OF TRAINING WALL TREES.

PEARS.—After having decided what varieties are most likely to suit the position, still further thought ought to be bestowed upon the selection of the trees. What buyers should stipulate for is medium sized comparatively young trees, and not extra strong overgrown specimens. The latter may fill more space, and even arrive at a bearing state during the first or second season after planting, but they are far from being the best in the end. As an instance we will take a horizontally trained tree with three, or it may be four, pairs of branches. These being very stout, and the side branches somewhat long and rigid, are not easily drawn up together when packed, a proportion of them as a consequence being badly damaged in the transit. The roots also of large trees are not often when received proportionate to the top growth, and the subsequent progress of these trees is usually very unsatisfactory indeed. Younger trees with their more pliable branches are much less liable to injury during their journey to fresh quarters, and being sufficiently well furnished with roots very little check is experienced in their removal, so that they are not long before they surpass the more stunted old trees. It would be an impossibility to me to point out better Pear trees both against walls and in the open than are to be seen at the Cardiff Castle Gardens, and I believe the whole of these were originally planted as maidens. Mr. Pettigrew, the gardener in charge, is, however, an experienced skilful grower, and it is not to be expected that all can successfully emulate what he has done. But if all cannot succeed with maidens, or trees that have had one clear season's growth from the graft or bud, as the case may be, this is no reason why the other extreme should be followed, or much too old trees planted.

Although there are several other methods of furnishing walls with Pears, none is so popular as the good old plan of espalier, or horizontally training, and it is of this system I will first treat. Trees that I have found do nearly as well as maidens are those that have been twice cut down, these being furnished with two pair of branches and a leader. The latter being duly shortened to about 12 inches in length should next summer produce two well-placed side branches and another leader, and in this manner a fresh pair of branches, or even two pair where the summer growth is sufficiently early and firm to admit of the leader being cut back in July every year. If maidens instead of three-year-old trees are planted, these must be cut back to within 4 inches of the stock and side branches, and leaders selected and laid in as advised in the case of the older trees. Supposing either of these young trees are well planted and cared for, they are capable of forming leading shoots from 24 inches to 30 inches long for several summers in succession, the branches and main stem presenting a clean healthy appearance, fruit of the best quality following in due course.

For covering walls quickly there is nothing better than one, two, or three-branched cordons, these being planted so as to bring the leading branches about 15 inches apart. Single cordons can be had by simply ordering maiden trees, any side shoots on these

being shortened back, and the leader laid in to its full length each season till the limit is reached. Two-branched cordons can also usually be formed from maidens without cutting back, the best placed lower branch on the upper side being laid in. This will naturally be weaker than the leader for several years, but will eventually overtake it. Three-branched cordons may be formed by cutting maidens back to within 4 inches of the union of graft with the stock, a central and two side branches being selected and laid in during the next summer. Young trees that have been once pruned, a leader and two side branches being selected and trained, can be bought from any nurseryman who prepares horizontally trained trees, and these are well adapted for training as three-branched cordons. As a rule, cordons succeed best when trained obliquely, the slight depression serving to better regulate the flow of sap than is the case when the branches are trained uprightly. The buttresses of old walls, as well as various archways and numerous blank spaces to be seen on most walls between the old horizontally trained trees, ought always to be furnished with cordons. Not only will the latter give a finished appearance to the walls, but the chances are they will also produce much the finest fruit.

Palmette verriers, which may be described as a combination of the horizontal and cordon systems of training, are not nearly so often seen as they ought to be. It was Mr. Luckhurst, I believe, who first strongly advocated them in the *Journal of Horticulture*, and it is to be hoped many more have given them a trial than I am aware of. Amateurs especially will find them singularly easy to train, the start being made either with newly bought-in small horizontally trained trees or some of the latter already well established, or even maidens may soon be converted into handsome trees. Any number of main branches may be laid in, say about 12 inches apart, the trees being planted so many feet apart accordingly. I consider six main branches a good average number for a tree, especially if the walls are upwards of 12 feet high. The foundation of a tree may be formed in exactly the same way as advised in the case of those horizontally trained, the only difference being that no central branch or leader should be laid in when sufficient side branches are obtained, the latter faring better when there is no leader to absorb the lion's share of the sap. Supposing there are six or more branches, the central pair would be trained 12 inches apart and nearly uprightly, the only curve being near their starting point. The next pair would have to be laid in horizontally, and then trained uprightly at a distance of 12 inches on each side of the central branches, and so on until all are given their proper position. The lowest branches of all naturally have much the greatest distance to travel in a horizontal direction before the points are given an upward turn. A very little examination of the system ought to convince anyone how easily moderately large trees now horizontally trained may be much improved in appearance and character, the sap being more evenly disposed throughout the growth, the lower branches eventually becoming nearly as stout as those apparently more favourably located near the centre. We have received stiff overgrown, then subsequently stunted, trees from nurseries that do not lend themselves to this method of training, and we also object to any with stems more than 9 inches in length. We have also grown good trees from two-branched maidens, and also by cutting down maidens in order to obtain two strong shoots, these being laid in right and left in a horizontal direction to a distance of 30 inches from the stem or centre, and then given an upright turn. The trees being fairly vigorous, depressing causes the branches to break strongly, and from each two well placed shoots are laid in at regular distances, and trained uprightly, a well formed six-branched tree being eventually thus obtained.

Fan-shaped trees are frequently to be met with, and though somewhat irregular, and not always pleasing to the eye, many of them are yet profitable. If the start is made with a well-branched young tree all that is necessary is to lay all the sound branches in to their full length at regular intervals over the wall, young shoots being laid in according as the trees widen and more wall space requires filling. This plan answers well with such strong growers like the Jargonelle, which are not easily trained in a more formal manner. If maidens are planted these must be cut back for two or three seasons, or till about ten main branches are obtained. In each and every case I hold it to be unwise to stop or prune the main branches in any way unless for the purpose of obtaining more in number. Laid in to their full they are more certain to form fruit buds freely and much less wood growth than would result if pruning, however lightly done, were resorted to. Stopping strong shoots is more likely to favour rather than to check their grossness, but early summer stopping of the lateral growth undoubtedly strengthens the weaker leaders. Trees on the Quince stock are the first to become productive, and are the best in all cases where head room is limited, but those on the Pear stock are more constantly

vigorous, and by timely root-pruning can be brought to and long maintained in a productive state.—FRUIT GROWER.

EMIGRATION OF GARDENERS.

(Continued from page 105.)

PROSPECTS.—A competent gardener—namely, a person who has served an apprenticeship under a good gardener, been journeyman or assistant in two or three, and foreman in at least one establishment, and possessing satisfactory testimonials, being of good health physically and mentally, of good education and address, and being furnished with the needful for a start in life, will do well to think twice before emigrating. Our prompter states that those expecting to secure charge of large establishments with a corresponding staff, will find situations affording scope for their energies and abilities very few in the United States of America, the President not employing more than a dozen hands in gardening at the White House, Washington. There are, of course, a few places, perhaps half a dozen in the environs of New York, and others of the older and larger cities, the proprietors being millionaires, where the establishment can compare with good gardening establishments in England. Even places keeping a gardener and two or three assistants are not nearly so plentiful as here. The greater number of situations are single-handed, and single men are preferred, a wife being as much an encumbrance as a large family is to a gardener in England, and the man must be utilitarian—namely, able and willing to attend to cows, pigs, poultry, horse and trap (waggon), making himself generally useful. In brief, the man most in demand from a gardening point of view for private places is a handy fellow that can turn his hand to everything the proprietor requires. Many such are only engaged for the summer months, April to November inclusive, the remainder of the year the gardener is left to shift as best he can. In such places 35 to 45 dols. per month are paid with board. There are no fixed hours of work, the employed must give up all his time from daylight to dark to the service. In winter employment can be had by those not having a permanency at odd jobs or with a florist at 1 dollar per day without board, and generally enough can be earned in winter for making ends meet, otherwise living must come out of the summer earnings. The foregoing remarks apply to all large cities on the Atlantic seaboard from Portland in Maine to Norfolk in Virginia.

It is with a florist that the gardener from these shores can do best in America, and acquire work suitable to the English taste. A good all-round hand can obtain ready employment and good remuneration—namely, 20 cents per hour for jobbing work, which of course applies to the summer months only, as in winter only occasional employment can be relied on. Professional florists can command high wages, and, of course, constant work, but this applies only to those that have become acclimatised, have knowledge and experience of the American florists' *modus operandi* and the ins and outs of trade.

Living is much the same in large cities and their environs as in England, rations being plentiful, good, and cheap; boarding, &c., being rather poor and high priced. Clothing, for better class goods, is high priced, but the Yankee dresses well and makes a point of wearing a thing only so long as it is decent, and then goes in for "spankers." Warm clothing is, of course, necessary for winter, and of this there is an "immensity of shoddy." The summers being hot and long cotton goods are all the go, as something must be had that is light and airy and will wash, as they have to be often changed.

A very large business is done in the large cities, particularly in New York and Philadelphia, in cut flowers. Tea-scented Roses are prized by everyone and grown extensively, as also are Carnations, Bouvardias and Gardenias, bulbs of all kinds, Callas, &c. Palms for decoration are grown largely, Smilax (*Myrsiphyllum*) taking the place of Adiantum, which with *Asparagus plumosus nanus* afford the requisite greenery and relief. Coloured foliage is much in demand for decoration, particularly *Ampelopsis Veitchii*. Easter decorations are much in vogue, enormous quantities being grown for that purpose of *Lilium Harrisii*, along with *Spiraea japonica*, *Deutzia gracilis*, and white (Indian) Azaleas. In spring the Violet and Pansy are much appreciated. Pansies do remarkably well, being raised from seed sown in spring and grown in frames during the winter, similar to Violets, in which they are flowered, being highly esteemed for cutting. To summarise, we may say the Americans aim at a good display of flowering and decorative plants in winter under glass, and use them—i.e., Crotons and all stove decorative plants, outdoors in summer, their colours coming out finely under the semi-tropical sun.

Carpet bedding is well, even excessively, done. *Alternantheras* being very bright in colour, also *Coleus*, *Echeverias*, and *Semper-*

vivums doing remarkably well. The attempts at that sort of thing in the London parks are simply "abortions compared with those of Philadelphia." *Caladium esculentum* was noted as singularly effective, and beds of named *Caladiums* are fine in sheltered situations. Cannas are much employed. Double-flowered Zonal Pelargoniums do magnificently, being masses of bloom, but the single are seedy. Fuchsias are done well, and are grand. Heliotrope is perhaps finer there than anywhere, and no flower commands more favour or deserves more.

"The 'homes' are mostly verandahed, and clothed with climbers, as Passifloras and Honeysuckles; but Vines are the great feature of American 'homes.' They are used for covering trellises, forming arbours essentially for shade, being accorded every cultural attention in order to have a crop of fruit. American varieties are grown, the European sorts being grown under glass, and are miserable examples. Fruit, however, is not much grown (or forced) under glass. Good early Peaches are grown under glass in pots around Boston, Alexander and Hales' Early being the principal varieties.

Vegetables are much in request, Asparagus being the first in the market, as there are no winter vegetables, except of course roots and preserved. Cauliflower is the most esteemed of early summer vegetables. The seed is sown in heat in February, kept there, pricked off when in rough (second) leaf 3 inches apart, and kept in heat until established, then hardened off in cold frames. When large enough to plant out they are put out in frames in rows 2 feet apart, and 18 inches asunder in the rows. The bed is formed of manure, with 4 inches thickness of loam over it. The plants are protected from frosts and sharp winds, but air is given on all favourable occasions, so as to insure a sturdy growth. The surface of the bed is mulched with cow manure, and the plants well supplied with water and liquid manure. If the plants have a tendency to draw up in the stem, and run to leaf instead of forming heads, a knife-blade is thrust through the stems vertically, to check the growth and induce the early formation of heads. Snowball in an esteemed variety, which comes in early in June. The heads are highly prized and priced, good examples bring 35 cents, and superior often 50 cents. All the seed is imported.

Early Peas are good, and follow Asparagus, the New York gardeners being expected to have with certainty Pears, new Potatoes, and Sweet Corn by the 4th July, as it is Independence Day, the great holiday of the Yankees. Peas are no good in summer, but they are useful in the fall. The "run" in summer is on Lima Beans, the bean being used green, not the pod as here with Scarlet Runner and French Beans, and the Beans are also used when mature. Dwarf and Runner Kidney Beans do well. Haricot Beans are grown for the seed, and the pods pass muster upon occasion of scarcity. Two crops of Cabbages are grown. The first is raised in heat similar to Cauliflower in February and March, but instead of placing them out in frames they are planted outdoors after being hardened. Another sowing is made late in July or early in August, planting out at the end of that month or early September for autumn and winter use. The plants are lifted in early winter, and are stored in dry earth in cellars, all the outside leaves being removed, the heads being available for use through the winter, and keeping them in good condition until spring.

The Lima Bean is tender, not being sown until the second or third week in May, a rather warm and dry situation being chosen, the greatest care being given to keep the seed right side up—i.e., the root downwards. A hillock is raised, placing about half a barrowload of manure to each, covered with sufficient soil to sow the seed in. A stake 8 feet high is placed in the centre of each hillock, the hillocks being 4 feet apart every way. Three or four seeds are placed around each stake, and thinned to two plants; but this is an extravagant plan, though the results are superior to the ordinary method of placing eight to ten beans in the hillocks, which ordinarily are not manured, about 3 inches from the stake, and when showing the runner the plants are reduced to five or six to each hillock. The Beans are highly esteemed when boiled similar to Green Peas, and served with melted butter. When dried the Beans are soaked in water overnight, so as to soften them before boiling.

Squash seed is sown on hillocks 10 feet apart, with half a barrowload of rotten dung to each, just covering with soil for sowing the seeds, three or four being placed in each hillock, thinning to two. Melons and Cucumbers are treated similarly, only the Melon hills are 6 feet apart and the Cucumbers 4 feet. The Melons grown are Cantaloupe, Water Melon, and Citron, the Citron keeping good until Christmas, and as far north as Maine.

Tomatoes are extensively grown, being raised in heat from a sowing made in March, grown on, and strong plants are placed out in May 3 feet apart every way, two or three stems being allowed to each plant, stakes being used in some instances, but generally

not, as the plants grow much more woody and bear up better than in England. Fruit of 1 lb. and over are not uncommon, the red sorts are chiefly grown, the yellow being rare.

Lettuce seed is sown in late August or early September, and good Lettuces are had by Christmas, which keep all the winter, but the ambition is to get good heads in spring, the plants having nice heads at Christmas, affording splendid ones in March and April. The plants are of course grown in frames and protected. A succession is maintained by a later autumn sowing, wintering in frames, and these keep the bowl going until the spring-sown come in. In summer there are no Lettuces, it is too hot and dry.

Celery is grown largely, the ground being heavily manured. A drill is made with a plough at every 3 feet, and the plants placed out 8 inches apart, which is not done until they are large, the tops being cut off, watering well after planting. No attempt is made at blanching until about five weeks before being required for use, and then all at once. Before winter sets in the Celery fit for use is lifted, not retaining any earth to the roots, storing away in sand or dry earth in cool dry place, but safe from frost. For late use the Celery is grown in butts, covered with straw before severe weather 1 foot thick, with boards to throw off wet. There are ventilators along the butts at every 10 feet. The Celery is, of course, earthed before being covered, and it keeps first rate and is used in spring. Radishes are grown in frames for early use, and sown outdoors in spring and fall.

Egg Plants are much esteemed, the fruits being fried, and have a pleasant flavour. The seed is sown in March in heat, pricked off in seed boxes, and the seedlings planted out in May 2½ to 3 feet apart, the ground having been well manured. Capsicums are treated similarly, only planting them 2 feet apart. The pods are used green, sliced, with vinegar, salt, and pepper.

Roots do well, particularly Potatoes, of which there is none better than Myatt's and Early Rose, with Magnum Bonum and Fluke. The fancy sorts are much the same in America as England, things to talk and write about, a kind of "seven-days wonder." Onions do capitally, also Beet, and Carrots with Parsnips. Globe Artichokes are no good, but Jerusalem are particularly fine in crop and quality.—UTILITARIAN.

(To be continued.)

CARNATION SOUVENIR DE LA MALMAISON.

(Continued from page 105.)

THE time for the next layers to be made will be from July to the beginning of September. The sturdiest plants will be produced from those layered out of doors, and at the earliest time mentioned it is advisable to root them in the open. The later will be, however, much better for the protection of sashes. Under these roots are formed very rapidly, care being always taken to keep the soil equally moist, and a little shade from sunshine is also advantageous. The best of these plants grown and repotted until 7-inch pots are reached, produce capital single-stemmed plants, which bloom from spring until the end of summer. Weaklings should be pinched. These are capital for producing big plants, and must be kept growing slowly through the winter, repotting when necessary, and treated to another pinching during summer, when fair-sized plants in 9 or 10-inch pots will reward the cultivator the second year. It may be noted here that two-year-old plants produce better blooms than younger ones do. They are not any larger certainly, but are more compactly built and of better shape.

As to the best compost, I find they thrive very well in one made of one part yellow loam, one part hotbed leaves and flaky leaf soil, and half a part of sand. I never add dung, but feed mainly with superphosphate applied at short intervals as a surface dressing. In potting the soil is not made very firm, and I have found firm potted plants do less well than those which have been less firmly potted. Dryness of the soil is very bad. In a fairly moist condition the soil is alive with rootlets covered with the finest of root hairs, and dryness means the destruction of every one of these at the expense of the quality and size of the flowers and the health of the foliage. One of the great features of Malmaison is the extraordinary size to which the blooms expand, but the largest blooms can be secured only by limiting the number left to develop. A Malmaison in rude health continues to produce fresh crops of buds in succession from the base of the older buds, and if these are left to grow without thinning it is impossible for the healthiest plant to bring any of them out to a large size; it is therefore absolutely necessary to disbud, and the stronger the plant the more disbudding must be done. A good bloom should be about 4 inches across. The biggest I have ever had was exactly 6 inches, but extra large ones are about 5 inches, so that it will be apparent that thinning is as necessary for Malmaisons as for any other flower if big blooms are wanted.

Another great point is to allow them plenty of time. If the plants are forced to spindle up it will be at the expense of size and quality; but if kept merely moving, with plenty air at all suitable times, good blooms may be fairly looked for.

As to what are Malmaisons, it might be thought there would be no question; but that is not so. I have bought at least six spurious varieties, four of which were from the continent. The *Souvenir de la Malmaison* Carnation is of a bluish white shade with a strong clove scent, distinct in foliage, in growth, and in its inflorescence. Of this there is a sport of a rosy pink shade, known as the Pink Malmaison; this is a beautiful variety. The former is catalogued on the continent as "Blanc," the latter as "Rose." There is also a sport from the pink variety named Lady Middleton. This is the pink form with clearly defined blush stripes. I have not seen this in continental lists. During the present winter a Brussels firm has distributed a true sport, with flowers of a vinous red, named Madame Warocqué. This will be an acquisition of the greatest value, and will no doubt become as popular as the other better-known kinds. A fifth variety is in the market; this is named The Witley Court variety. I have not had an opportunity of seeing this, but it is either the pink form, or else very like it in every respect.—N. B.

IMPROVING LAWNS.

I NOTICE in your recent issues a few remarks on this subject. May I, as an ex-farmer, and one who has had some experience in grass land, grasses, and laying down land to permanent pasture, venture to make a few remarks also? I have always treated my lawn in the same way as I treated my grass fields or meadows that I was constantly in the habit of mowing, and I think if people would treat their lawns in the same way they would find my system to be right. A farmer who mows certain fields year after year knows that unless he manures them constantly his stock of hay will become abundant and his land poor; but it never seems to strike the majority of people who have the care of the lawn that if they constantly mow the lawn must eventually suffer. That Daisies, Dandelions, and other weeds will take the place of the finer grasses is a certainty if the lawn is allowed to get in an impoverished condition, for most weeds thrive best on poor soils. It only stands to reason that this must be the case, and if people would feed their lawns in the same way as the farmer feeds his fields, comparatively speaking, instead of a poor yellow-looking piece of turf they would have a green velvety piece of sward.

It is quite useless to sow expensive grasses and Clovers on land that has no virtue in it, the result will only be disappointment and waste of money. But if a good dressing of cow manure or road scrapings is applied to the poor lawn for two or three years consecutively, and after that every other year, you will find the Daisies, moss, and Dandelions disappear, and good grasses and Clovers take their place. I know of no better manure than road scrapings applied in a dry state for the tennis lawn. Sulphate of ammonia, superphosphate, and such like, are only stimulants, and act on poor land like brandy does to the dying man. Soot is a good and valuable manure for the lawn, but it will not make poor land rich, and should be used when you have got your lawn round; and my advice to those whose lawns are in a poor state is, See that they are properly drained and then feed them, remembering that if you reap you must sow, and if you mow you must apply manure.—EX-FARMER.

HYBRID ORCHIDS.

HYBRIDISM furnishes horticulturists with one of the most interesting studies in connection with plant life, and its commercial importance can scarcely be over-estimated, for amongst both useful and ornamental plants skilled hybridists have produced astonishing results. The fact cannot, however, be disregarded that after the exercise of every care and thought in effecting crosses for definite purposes, selection becomes necessary, and much depends upon the way this is performed; keen critical observation must be enlisted in the service of the would-be plant improver, or much of his labour will be lost. A celebrated breeder of dogs was once asked to explain his uncommon success, and he replied, "Oh, I breed a great many and I hang a great many," and the success

of some plant raisers could be summarised in similar terms, as in any experiments there is sure to be a large proportion of seedlings that must be rejected, and the greater the number raised the better the chance of obtaining those worth preservation. Some have succeeded in adding many beautiful novelties to our flowering plants simply by selection from a great number of seedlings raised annually for several years, and by indiscriminate crosses. There can be no doubt, however, that much more may be accomplished by an intelligent and methodical system of crossing than by any haphazard mode of working, and every credit is due to those who within the past quarter of a century have assisted so much in the development of new and improved plants by means of hybridising.

One of the most important matters in regard to this subject is the relative influence of the pollen and seed parents; but though the subject has been treated exhaustively by highly competent observers, the numberless facts are so varied, and indeed so contradictory, that it is impossible to draw up any rules applicable to plants generally. In many cases it has been proved that the characters of the seed parent greatly predominate in the seedlings obtained by crossing with pollen of another species or variety. A skilful and successful hybridist, who has for many years been concerned in the production of florists' flowers, such as Chinese Primulas, Cyclamens, and Cinerarias, gives as the result of his experience that three characters out of every four in the progeny from a cross will be due to the seed parent. This he proved to my satisfaction by reference to records of crosses extending over ten years, and showed conclusively what a methodical plan and continued perseverance can accomplish, for in nearly every case he had succeeded ultimately in attaining his object. Mr. Peter Grieve, who performed good service amongst the variegated Pelargoniums, has stated that in his opinion the constitution of a plant is chiefly due to the seed plant, and he attributes the delicacy of many of the Pelargoniums named to the employment of the plants with variegated leaves as seed bearers. He further says, "The most vigorous and in all respects the best I have raised have been from green-leaved seed parents." This we can easily understand, but my observations teach me that considerably more depends upon what may be termed the individual characters of the seed plant than upon the specific or varietal distinctions. Thus the selection of a strong healthy plant for seed-bearing is likely to give better results than a weakly individual of the same species, whatever the cross may be.

A peculiarity has also been observed that is in a measure confined to the plant world—namely, when a cross has been effected between two species and resulted in the production of seedlings possessing well marked characters, the reverse cross has given practically the same result. This seems somewhat contradictory to the above statement respecting the influence of the seed parent, but it is true, though of course it applies chiefly where the characters of the two parents are nearly balanced in the seedlings. Amongst the Orchids this comes out strongly, and it may be safely asserted that in three-fourths of the hybrids raised little difference is caused by reversing the crosses. Such is the experience of the most successful Orchid hybridist of the present time, and it is the more remarkable when the very strongly marked characters of the majority of Orchids are considered. In some cases there is a predominance of one parent, but they are few, and do not seem to follow any rule.

No family of plants presents so many interesting points in hybridism as the Orchids, and it would be impossible to review them all even briefly in the limit of a paper like this. The subject has also been exhaustively dealt with by such authorities as Mr. H. J. Veitch, which renders it all the more difficult to say anything fresh. But to illustrate some of the chief phenomena in Orchid hybridising I have selected two genera—the *Odontoglossums* and the *Cypripediums*—which have given most diverse results under artificial treatment. First, as regards the *Odontoglossums* we have two curious facts to consider, one is that numbers of *Odontoglossums* are found in a wild state so exactly intermediate in floral form and colouring between other well known species as to leave no reasonable doubt that they are natural hybrids, they have been introduced freely, and have puzzled botanists and horticulturists not a little. The other fact is that notwithstanding this evident variability and tendency to intercrossing in a wild state, the *Odontoglossums* have not yielded to the cultivators' attempts to obtain hybrids under artificial conditions, indeed they have stubbornly resisted all efforts, and have caused more disappointment than any other Orchids. Seedlings have been raised in a few instances, but invariably lost, and the strangeness of this circumstance induced me a few years ago to make some experiments with a view to testing the matter. I had several healthy plants of *Odontoglossums*, and amongst them were six each of two favourite species—*O. Pescatorei* and *O. triumphans*. They were in good condition for

experiment, flowered well, and if a cross could be effected they gave a promise of something worth securing. Yellow forms of the *O. Pescatorei* type had been introduced, and one charming variety, for which Mr. Brownlow D. Knox obtained a first-class certificate from the Royal Horticultural Society on April 13th, 1886, impressed me greatly, and the impression was intensified when the same plant realised £165 at a public auction the next day. There was little doubt that *O. triumphans* or *O. tripudians*, most likely the former, had conferred the yellow colour, and it did not seem too much to expect similar results from an artificial cross. Three of the strongest plants were selected of *O. Pescatorei* and of *O. triumphans*, and two flowers of each were reciprocally fertilised—*i.e.*, the pollen of *O. Pescatorei* was placed on *O. triumphans*, and *vice versa*, thus twelve flowers were fertilised, and to my great satisfaction it appeared to be effectual with nine, for in the course of a week the ovaries were perceptibly enlarging. They were carefully watched, and as they slowly advanced golden visions began to rise of a few thousand yellow flowered plants of *O. Pescatorei*, and these hopes were sustained for nearly six months, when the capsules, which were then well developed, commenced shrivelling, and upon examination were found to contain nothing in the shape of fertile seed.

With the other plants of the two species named a different experiment had been tried—namely, seven or eight flowers were fertilised with their own pollen or with that from other flowers on the same spike, but in only one case was the ovary in any way affected—*i.e.*, where a flower of *O. triumphans* had been fertilised with pollen from another flower on the same plant, and in this instance the development only lasted for a week or two, and the capsule then collapsed as in the previous case. These experiments were interesting as proving what Darwin and others have recorded—namely, that pollen often has the power of affecting the ovary, though it cannot influence the ovules, and cases have even been described where the ovules too have been affected, but no embryo produced. Experiments were tried with several other *Odontoglossums*, but without success, except in one instance, between *O. Cervantesi* and *O. Rossi majus*. A flower of the former was fertilised with pollen from *O. Rossi majus*; on March 29th, 1888, a capsule was produced, which slowly developed and ripened until June 30th, 1889, when it commenced dehiscing. The pod was then removed, and was found to be packed with minute seeds, which when examined under a glass appeared to be perfect. In the course of the following week the seed was sown, and now a few diminutive seedlings are just visible. The reverse cross failed to produce any result, and in any case the seedlings from such parents are not likely to possess any special merit even if they survive, which is doubtful. These experiments are only examples of many others that have been attended by similar results; even Mr. Seden has found his skill of little avail, and yet these beautiful puzzling natural hybrids are being continually introduced. The *Odontoglossums* are certainly very remarkable in this respect, for though they have been employed with many other Orchids the results are invariably the same. Perhaps the most extraordinary part of all is that pollen of some of the *Odontoglossums* has been used to fertilise flowers of *Zygopetalum Mackayi*, every care being exercised to prevent self-fertilisation, yet though seedlings have been obtained they have all been identical with the seed bearer, and I have heard very emphatic language employed with regard to the *Zygopetalum* by disappointed hybridists, who had been waiting in vain for different results.

So much for the artificial attempts to secure hybrid *Odontoglossums*. Now turning to the imported plants we find that the following have fair claims to be considered as hybrids:—*O. brachypterum*, between *O. Pescatorei* and *O. luteo-purpureum*; *O. elegans*, between *O. cirrhosum* and *O. cristatum*; *O. eugenes*, between *O. Pescatorei* and *O. triumphans*; *O. excellens*, of similar parentage, and one of the most handsome yet obtained; *O. Horsmani*, the same parentage as *O. brachypterum*; *O. Murrellianum*, between *O. naviu*m and *O. Pescatorei*; *O. Schrederianum*, between *O. tripudians* and *O. Pescatorei*, a very distinct and beautiful Orchid (fig. 20); *O. stellimicans*, similar parentage to *O. excellens*; *O. vexativum*, between *O. maculatum* and *O. nebulosum*; and *O. Wilckeanum*, between *O. crispum* and *O. luteo-purpureum*, one of the best of the whole group when represented by a good variety. It is strange that so many show the *O. Pescatorei* parentage, and it frequently happens that they exactly resemble that parent in habit and foliage. Some of the finest of the hybrids have appeared amongst importations of *O. Pescatorei*, and a short time since a flower was sent to me from a plant in an importation of that species with rich yellow sepals and petals and a few dark spots, clearly showing the influence of a cross either with *O. tripudians* or *O. triumphans*.

In direct contrast to the *Odontoglossums* are the *Cypripediums*, as regards the facility of obtaining hybrids under artificial con-

ditions, for nearly half the known hybrid Orchids have been obtained in the genus *Cypripedium*, and their numbers will in a few years be greatly increased. These have been so frequently referred to that it is not necessary to recapitulate what I said last year on the subject. There is one matter, however, which deserves attention, and that is the comparatively few wild forms of the genus which can be ranked as probable hybrids. The only ones that occur to me are *C. Curtisi*, which possesses characters intermediate between *C. ciliolare* and *C. superbiens*, and the companions *C. Godefroyæ* and *C. bellatulum*, which present a combination of the chief features in *C. niveum* and *C. concolor*. With these exceptions the majority of *Cypripedium* species known to me are very distinct, or if they show their relationship to some other species, there is no combination of characters, and they might be better regarded as varieties than as hybrids. Yet under cultivation everyone knows we have some most remarkable and charming combinations, not only between pure species, but between them and hybrids, and even between hybrids themselves. Why there should be this great difference between the *Cypripediums* and *Odontoglossums* it is impossible to say, and we can only conjecture that some condition is wanting for the latter, and until that is supplied failure may be expected. A large majority of Orchids are obviously

FIG. 20.—ODONTOGLOSSUM SCHREDERIANUM.

especially adapted for cross-fertilisation, and it is difficult to understand why that cannot be as well accomplished in our houses as in the heights of Mexico or South America. It is true that a few Orchids are habitually self-fertilised, especially some of our hardy native species, but the *Odontoglossums* seem wanting even in this power under cultivation. Some of the *Ophrys* and *Orchises* become sterile when transplanted, and one species has been observed to be fertile in one district and sterile in another; but no explanation has yet been offered of these mysterious occurrences, and they must be included with the numberless phenomena which render the Orchids a source of perpetual interest to the thoughtful cultivator.—LEWIS CASTLE.

ROYAL HORTICULTURAL SOCIETY.

JANUARY 11TH.

MANY exhibits of interest were arranged in the Drill Hall on this, the second meeting of the year; Orchids, in which variety, beauty, and good culture were represented; Hellebores in great variety; various early hardy spring flowers; Cyclamens of the first quality; a picturesque assortment of standard, dwarf, and berry-bearing shrubs, with a good collection of Apples. There was also a large assemblage of members, attracted largely, no doubt, by the annual general meeting of the Society, which was held during the afternoon.

FRUIT COMMITTEE.—Present: Sir Charles W. Strickland, Bart. (in the chair), and Messrs. John Lee, A. W. Sutton, P. Crowley, Harrison Weir, R. D. Blackmore, J. Cheal, P. Barr, W. Bates, F. Q. Lane, J. T. Saltmarsh, G. W. Cummins, J. Hudson, J. Smith, G. Bunyard, W. Dominy, Sidney Ford, and J. Wright.

Mr. W. Leach, Albury Park, sent a dish of Ham Green Favourite Tomatoes, cut from plants sown in September, and a cultural commendation was awarded; he also sent large Coldstream Leeks, and was accorded a vote of thanks. Mr. Arthur W. Sutton proposed a vote of condolence with Mrs. Wildsmith on the loss of her husband, who was a valuable member of the Committee, and attended the last meeting. The proposal was seconded by Mr. J. Hudson, supported by Mr. G. Bunyard, and passed unanimously.

Messrs. J. Cheal & Sons exhibited a collection of forty-five varieties

of Apples, consisting generally of large, well coloured, and well kept fruit, for which a silver medal was recommended.

FLORAL COMMITTEE.—Present: W. Marshall, Esq., in the chair, and Messrs. R. Dean, T. Baines, C. T. Druery, H. B. May, P. Blair, W. C. Leach, R. B. Lowe, B. Wynne, H. Turner, G. Paul, G. Nicholson, F. Ross, W. Holmes, E. Mawley, T. W. Girdlestone, and W. H. Williams.

The exhibits before this Committee were not numerous, and consisted chiefly of the early flowering hardy plants and bulbs. Hellebores were well represented from Mr. J. Douglas, Great Gearies Gardens, Ilford, who had a number of varieties of *Helleborus guttatus* (vote of thanks). Mr. W. C. Leach, Albury Park Gardens, Guildford, contributed a collection of *Cinerarias* and *Violets*, the varieties *Marie Louise*, *De Parme*, and *Swanley White* being included amongst the latter. He also had plants of *Azalea obtusa* and *Andromeda floribunda* (vote of thanks). From Messrs. Paul & Son, Cheshunt, came a fresh bright group of hardy plants that were quite spring like in appearance, though some must have had shelter. Hellebores were excellent, as also were the hardy *Cyclamens*, *C. Coum zonale* (vote of thanks) especially so, and a deep purplish red Hellebore, named *colchicus coccineus* received an award of merit. Irises of the *reticulata* type and *Hepaticas* were also noteworthy. Messrs. Barr & Son, King Street, Covent Garden, staged some varieties of Hellebores, the brilliant *Anemone fulgens*, and the smaller early *Narcissi*. Messrs. H. Cannell & Sons, Swanley, sent plants of *Primula sinensis* *Swanley Pink*, a single variety with exceptionally large substantial flowers. The St. George's Nursery Company, Ealing, had a group of well grown *Cyclamens*, compact in habit, and bearing large flowers (bronze medal), and Messrs. C. Lee & Son, Hammersmith, supplied a tasteful group of ornamental shrubs, amongst which *Aucubas* in fruit, *Hollies*, *Euonymus*, and *Ivies* formed the leading features.

ORCHID COMMITTEE.—Present: H. J. Veitch, Esq. (in the chair), and Messrs. F. G. Tautz, F. Sander, F. Moore, Lewis Castle, J. Douglas, E. Hill, C. Pilcher, W. B. Latham, J. Dominy, H. Ballantine, H. M. Pollett, S. Courtauld, D. B. Crawshaw, J. O'Brien, and A. H. Smee. The display of Orchids was a surprising one, for at this time of year, and in such unfavourable weather, it is too much to expect that either amateurs or nurserymen will risk the exposure of their treasures. Happily, however, it seems that a desire exists to assist the Society, and increasing confidence in the Orchid Committee has apparently induced more exhibitors to submit their novelties to the judgment of the members. We do not remember seeing so many Orchids at any February meeting held by this Society. The whole of those shown cannot be particularised, but some of the best are included amongst the plants for which first-class certificates or awards of merit were granted, and are described at the end of this report. Messrs. J. Veitch & Sons, Chelsea, had a small group of hybrid Orchids, chiefly consisting of *Cypripediums*, representing the results of crossing *C. Spicerianum* with *C. villosum* and *vice versa*. The hybrid thus obtained was named *C. Lathamianum* a few years since because it first appeared in the Botanic Gardens at Birmingham under Mr. Latham's charge, but it has since been raised by others, and it was shown on this occasion from several sources. It was curious to observe that in both crosses the results were practically identical, the flowers varying somewhat in size and depth of colouring; but the chief difference was observable in *C. Calypso* from the same cross, with the exception that *C. villosum* Boxalli had been used as one of the parents instead of an ordinary *C. villosum*, the result being that more colour was infused into the dorsal sepal. *Phalaenopsis* F. L. Ames from P. amabilis and P. intermedia Portei was represented by a small plant bearing several neat and pretty flowers, while another hybrid—*Dendrobium Wardiano-japonicum*—from the two species expressed in the name, had a good deal of the latter parent in the flowers, which were, however, a little larger, and there was a deeper coloured blotch in the centre of the lip.

Mr. O. Thomas, Chatsworth Gardens, sent spikes of *Ceoloyne cristata* with seven and eight fine flowers each (vote of thanks). From E. A. Roberts, Esq., Woodland House, Greenhithe (gardener, Mr. J. Simon), came two varieties of *Lycaste Skinneri*, one named *Reginae* (award of merit), having rich crimson petals and lip, the other having larger flowers and a white lip, and *Cymbidium eburneum* had three of its handsome pure flowers (vote of thanks). The Right Hon. Lord Foley, Ruxley Lodge, Esher (gardener, Mr. Miller), showed a healthy well-flowered plant of *Ceoloyne cristata* (vote of thanks). H. M. Pollett, Esq., Bickley, had a plant of the interesting hybrid *Cypripedium Germinyanum* (certificated), an excellent variety of *Cattleya Trianae* and *Odontoglossum crispum* *bickleyense*, with large yellowish flowers heavily spotted with brown (vote of thanks); also a plant of the superb *Cypripedium Elliottianum*, which secured a unanimous certificate.

Sir Trevor Lawrence, Bart., M.P., Burford Lodge, Dorking, exhibited another of the attractive hybrid *Dendrobiums* which have been raised in his collection. This was named *Aurora*, but the parentage was not stated, though there seemed to have been some of the *D. moniliforme* characters. The flowers are of neat shape, the sepals and petals white tinted with purple, with a narrow blotch in the centre (vote of thanks). M. S. Cooke, Esq., Kingston Hill (gardener, Mr. D. Cullimore), had a group of Orchids, comprising *Cattleyas*, *Odontoglossums*, and *Dendrobiums*, well grown, and bearing good flowers. A. H. Smee, Esq., The Grange, Wallington (gardener, Mr. Cummins), sent several interesting Orchids, amongst which *Odontoglossum ramosissimum* (certificated) attracted much attention. *Cattleya Trianae* *Dayana* was also finely

represented (vote of thanks), and the peculiar deep-spotted *Masdevallia leontoglossa* (botanical certificate). W. Vanner, Esq., Camden Wood, Chislehurst, showed a group of Orchids, including *Dendrobium nobile* *Cooksoni*, *Odontoglossum Jenningsianum* *superbum*, *Lycaste Skinneri* *alba*, with ten pure white flowers, and *Cattleya Trianae* varieties, one named *Mariae* being notable for the rich colour of its lip (vote of thanks).

An extremely fine specimen of the useful old *Cypripedium insigne* came from H. S. Smith, Esq., Silvermere, Cobham, Surrey (gardener Mr. Quarterman). The plant was fully 4 feet in diameter, and had eighty-seven large flowers. A cultural commendation was deservedly awarded for this admirable example. Mr. Waltham, Streatham Hill, sent flowers of *Ceoloyne cristata* (vote of thanks), and G. Arbuthnot, Esq. (gardener Mr. Mitchell), Bridgen Place, Bexley, showed *Cattleya Trianae* varieties and *Odontoglossum Andersonianum* (vote of thanks).

CERTIFICATED PLANTS.

Cypripedium Elliottianum (H. M. Pollett, Esq.).—A grand acquisition amongst the *Cypripediums*, one of the *C. Rothschildianum* type, but distinct and very handsome. The sepals and petals are straw coloured or pale yellow, the dorsal sepal broad, oval, and with narrow maroon stripes radiating regularly from the apex to the base. The petals are long and tapering, spotted with maroon, especially at the base, the lip being after the *C. Stonei* style, and somewhat similar in colour.

Cypripedium porphyrochlamys (F. G. Tautz, Esq.).—There is something peculiarly fresh and pleasing in the colouring of the flowers of this hybrid, an uncommon violet purple hue suffusing the whole flower. The dorsal sepal is roundish, deeply veined with purple and edged with white; the petals are long, purple at the tip, and spotted with the same colour at the base on a lighter ground. The lip is well proportioned and of a soft purple tint.

Cypripedium Germinyanum (H. M. Pollett, Esq., and Messrs. J. Veitch & Sons).—A remarkable hybrid possessing very bold floral characters, distinguishing it amongst all those hitherto raised. It was obtained from a cross between *C. hirsutissimum* and *C. villosum*. The flowers are nearly 6 inches in diameter from tip to tip of the petals, which much resemble *C. hirsutissimum* in shape and colour. The dorsal sepal is very large and is green, with brown veins and markings, the lip suggesting *C. villosum* in shape.

Cypripedium Lathamianum (C. L. Ingram, Esq., Baron Schröder, F. G. Tautz, Esq., and Messrs. Veitch & Sons).

Though this has been shown before a certificate had not been awarded, as it was not considered sufficiently distinct. On this occasion it came from four exhibitors, that from Mr. Ingram being by far the best. It is the result of a cross between *C. villosum* and *C. Spicerianum*, and partakes nearly equally of the characters of the two species. It was described and figured in this Journal, page 175, February 28th, 1889.

Cypripedium cardinale, *Vanner's variety* (W. Vanner, Esq.).—A hybrid between *C. Sedeni candidulum* and *C. Schlimi*, with white sepals and petals, and a pink tinted lip. It is in the way of *C. cardinale*, but of lighter colour (award of merit).

Odontoglossum ramosissimum (A. H. Smee, Esq.).—A charming species that has been too long neglected, though it is not often seen in such fine condition as Mr. Smee had it. The sepals and petals are white, heavily dotted with bright purple, and are much undulated at the margin, the lip being similar. The flowers were borne in a large panicle, and the plant was strong in habit.

ANNUAL MEETING.

The annual meeting of the Royal Horticultural Society was held in the Council Room, 117, Victoria Street, Westminster, at 3 P.M., Sir Trevor Lawrence, Bart., M.P., being in the chair. There was a large attendance, and a very cordial and hopeful tone pervaded the meeting. The Secretary (the Rev. W. Wilks) read the minutes of the previous meeting and the names of upwards of fifty candidates for fellowship, who were subsequently elected.

The CHAIRMAN rose to make some remarks on the report. He thought that all who had taken the trouble to read the report had reason to be satisfied, and that the direction in which the Society was moving would recommend itself to every Fellow. The conferences had attracted a considerable amount of competition, although all present knew how difficult it was to secure an adequate response when prizes were not offered. The support from the public had not been satisfactory, and Chiswick did not appear to be a good place for holding those meetings. If held in a good and more central position there would probably be a better attendance than at present. With regard to the usefulness of the trial work at Chiswick, he would instance Tomatoes, in which a very large number of varieties had been reduced to about thirty. The Society still found themselves obliged to have shows, &c., at the Drill Hall. Inquiries had been made, but they had not been able to find a better place, although they had long felt that the present one was unsuitable for the exhibition of rare and valuable plants. However, the Council hoped soon to place before the Society a practical scheme for a horticultural hall. (Cheers). Baron Schröder would give information on this subject, and it would be greatly due to him if the project were carried to a successful issue. He (the Chairman) would also like to refer to the various lectures that had been delivered at the meetings. These had all been delivered by the most competent men in the several departments, and it would be impossible to over-rate the value of their services. He would say one word as to the Temple Show which had been a great success. There was a very fine display of plants

and Orchids, and they had every reason to hope that they would again have a show this season even better than that of last year. He referred to the more regular publication of the Journal of the Society. In former years country Fellows had complained of getting so little for their money; since the publication of the Journal they had received many letters expressing pleasure in it. One of their papers had been read before the Nantes Horticultural Society, and a discussion had taken place upon it. The Secretary and Treasurer had rendered valuable aid in editing this Journal, and he thought it would be impossible to have two more energetic, judicious, and in every respect, admirable officials. (Cheers). The library, which was open to all the Fellows, and was frequently consulted, had been placed in proper order. After referring to some items in the accounts, in the course of which he alluded to the improvements which had been effected at Chiswick, the Chairman concluded by expressing his deep sense of the loss the Society had sustained by the death of Professor Reichenbach, the Rev. M. J. Berkeley, Rev. J. T. Boscawen, and Mr. W. Wildsmith, whose places it would be very difficult to fill.

BARON SCHRÖDER then rose to give a preliminary sketch of the scheme by which they proposed to raise money and devote it to the building and maintenance of a hall of horticulture. Ever since the Society had left South Kensington they had, he said, been looking about for a suitable place, and though they had secured temporary premises the Society could not possibly remain as it was. A small Committee had been appointed to consider the matter, and the first question that arose was, How to raise the money? The second, How to obtain a site? It was agreed that if outside friends, as well as the trade, would provide a good sum of money—£30,000 or £40,000—a site could soon be obtained. This money, which would be lent by the Society's supporters, these receiving no interest upon it, would be invested in three trustees, and the interest upon it would insure the ground rent that would be required. They would then erect a hall, library, &c., and rooms suitable for the use of the Royal Horticultural Society and for special societies and institutions, for which rent would be paid. Moreover, if the hall were in a good position it might be let for various purposes without detriment to the Society. He did not think it desirable at present to make a definite statement as to the probable site, but he would add that they had one in view in one of the best positions in London, and which would be passed by the majority of persons going to and fro into the city. A love of flowers was undoubtedly increasing in the city, and he thought that if business men found pleasure in visiting shows they would soon decide to pay an annual subscription and enter them when they pleased. He (the Baron) felt most confident in the success of the scheme; so much so that he was prepared to give a considerable sum of money towards it, to form one of a Committee for working out the scheme, and, if the Society desired it, to become one of the trustees of the money. (Cheers.) If some such course was not adopted he thought the Society would decline. A turn for the better had now come, Fellows were increasing in number, and now was the time to get the Society a permanent home.

THE CHAIRMAN formally moved the adoption of the report, and Dr. Hogg, in seconding it, referred in terms of warm approval to the efforts that were being made to lift the Society into a better position, and to Baron Schröder's endeavours to formulate a scheme for providing it with a suitable home. No one, he said, was more competent to give advice on such a matter as this, which, in fact, was a small affair compared with many of the financial undertakings in which the Baron was engaged. He (Dr. Hogg) could now see daylight ahead in the affairs of the Society, and was delighted to observe the turn for the better that had taken place.

Dr. MORDAUNT MATTHEWS also spoke in support of Baron Schröder's suggested scheme. He would, he said, gladly offer £100 himself, and he had no doubt many other Fellows would subscribe.

Other gentlemen spoke in approval of the progressive policy of the Society.

Mr. D. MORRIS (Treasurer) in reply to a question respecting the affiliation of local horticultural societies, stated that the members of the Chiswick Horticultural Society (which was specially referred to) were admitted to inspect the Chiswick trials on payment of an annual sum, and also held a Show in the Gardens. Similar terms could no doubt be conceded to other societies, but the majority were too far away to find it convenient to avail themselves of such an arrangement. He also referred to the increased expenditure on postage. This had been necessitated by the regular issue and distribution of the Society's Journal. Formerly it had been handed to Fellows on application at the office; now copies were regularly posted to all subscribing Fellows. The clerical expenses of the Society had been much reduced, a result largely due to the energy of the Secretary. (Cheers.)

The report having been submitted to the meeting was unanimously adopted.

The election of officers was then proceeded with. Messrs. E. A. Hambro, N. N. Sherwood, and Martin R. Smith were elected to fill the three vacancies on the Council caused by the retirement of Messrs. J. R. Bourne, W. Coleman, and A. H. Smee. Sir Trevor Lawrence, Bart., M.P. was elected President, Mr. D. Morris Treasurer, the Rev. W. Wilks, M.A., Secretary, and Messrs. G. Deal, W. Richards, and H. Turner, Auditors.

A hearty vote of thanks to the President, Treasurer, and Secretary brought the meeting to a close, the proceedings terminating with bright auguries for future success. It may be added that as a result of Baron Schröder's suggested financial scheme, a subscription was opened towards

the close of the meeting, and a sum of £2600 was raised in the course of a few minutes.

DISEASE OF TOMATOES AS CAUSED BY FUNGI.

DURING the last few years many garden plants, including Tomatoes, have been badly attacked by so-called new species of fungi belonging to the genus *Cladosporium*. These species, described by botanists as new to science or new to this country, are very much alike in general appearance—in fact, they are so much alike that possibly no one could distinguish between them unless the names of the host plants were known beforehand. In the majority of instances leaf fungi are named after the plants on which they most frequently grow—in fact, the habitat is too often the very feeble foundation for the establishment of the species. This plan, as adopted by botanists, of giving specific names to leaf fungi is as bad as if all Buttercups found in chalky fields were called by one specific name, all in loamy fields by another, and all found in peaty fields by a third.

When seen upon the supporting leaves, and even under the microscope, there is often no difference whatever to be detected in some so-called species of microscopic fungi (as in *Puccinia*), and no botanist, however talented or imaginative, could name the fungi unless advised beforehand of the name of the plant upon which the fungus grew; for instance, a dozen microscopic preparations of so-called species of *Puccinia* might be forwarded for naming to a

FIG. 21.

DISEASE OF TOMATOES AS CAUSED BY *CLADOSPORIUM LYCOPERSICI*.

scientific authority, and no botanist would be able to give a specific name to a single example, or to distinguish one from the other. In this respect it will be seen that many microscopic fungi resemble many florists' flowers. If a specialist receives the name of the plant on which the fungus was seen he will then name (almost without examination) the specimens. The more puzzling species of fungi (as when two or more species of one genus grow upon one host plant) are named vexans, obscura, perplexans, inconspicua, &c.

There is a good deal of vexans, obscura, perplexans, and inconspicua about the Tomato fungi, as most gardeners by this time probably know. There is a very common microscopic fungus found on foliage of all sorts, named *Dactylium roseum*. It more or less covers the leaves on both sides with a fine pinkish-white powder, and to the unaided eye is not unlike the mildew of Vines, save in its very faint pink colour. Of late years this fungus has been far too common, and sometimes its growth upon Tomato plants has been profuse. This *Dactylium roseum* has a twin brother named *D. lycopersici*, chiefly so named because it grows with luxuriance upon Tomatoes.

Tomatoes have of late been flooded with fungi, for which new names have been invented. Some of these are without doubt very old friends with new names. For instance, there is a new *Sphaeronema lycopersici*, and a new *Sporocybe lycopersici*, a new *Cladosporium lycopersici*, a new *Macrosporium lycopersici*, and (for a slight change) a new *Macrosporium tomati*—all new forms, and peculiar to the Tomato if a student can only bring his mind to believe it. The Potato fungus sometimes grows upon the Tomato plant; when it does so it is not given as our old acquaintance *Peronospora infestans*, but *P. lycopersici*.

The fungus most worthy of attention when growing upon Tomatoes is the destructive parasite known as *Cladosporium lycopersici*. This fungus causes the decay of the fruit. It begins with a minute black spot, which surrounds the small decaying style. The black spot gradually increases in size by new circles of growth, one beyond another in the style of fairy-rings. The fungus growth at the same time flattens the apex of the fruit, till at last the whole substance is blackened and entirely destroyed by the *Cladosporium*. The fungus spreads from the leaves (as I believe), or from one fruit to another, till at last leaves, stems, and fruits are all alike rotten. A small illustration is here given (fig. 21) natural

size, of a half destroyed-fruit, and a view of the assailing fungus which has been named *Cladosporium lycopersici*, enlarged from the microscope 500 diameters.

The brown spores of this *Cladosporium* are often produced in such enormous numbers upon both sides of the foliage that they fly from the leaves in millions. If the Tomato foliage is briskly touched, a cloud of spores will taint the air and be distinctly perceptible in the mouth and lungs if they are inhaled.

But it would appear that *Cladosporium lycopersici* is not the only species which makes black spots upon Tomatoes, for Dr. Cooke has described a *Cladosporium fulvum*, which also causes black spots upon Tomato fruits. An ordinary human being might suspect these two fungi to be the same, and an ordinary botanist, on examining the published illustrations, might be able to see no difference between the two. Certain fungus-men will not however have it so, and one bold fungus-man has even had the temerity to suggest the existence of even a third species. On second thoughts, however, the latter gentleman modestly christened his would-be species a mere variety under the pretty name of *Cladosporium fulvum violaceum*. Whether all these wretched little fungi are quite the same with, or a trifle different from, each other, does not matter the toss-up of a button. It is sufficient for ordinary mortals to know that Tomatoes are attacked by a *Cladosporium* of some kind which grows upon leaves and fruit alike, and kills both. The fungi we are discussing are named *Cladosporium* because the supporting stems of the spores are (or, rather, should be) branched, from *klados*, a branch; but the fungus of Tomatoes is not branched, neither is the typical engraved species of *Cladosporium* in "Cooke's Handbook," but a considerable amount of unmitigated scientific botany is unfortunately got up in this style.

Let the botanists settle amongst themselves whether the Tomato fungus is a *Cladosporium*, a *Helminthosporium*, a *Macrosporium*, or a *Heterosporium*, or any other kind of "sporium," so long as they do not pester the poor inoffensive growers of Tomatoes with long-winded names and descriptions. It is all heterosporium (*heteros*, variable) to the writer of these lines.

Of late years liliaceous and even orchidaceous, and other plants, including garden Carnations, have been badly attacked by *Cladosporium*. The devastation caused of late by these attacks is certainly remarkable.

Most of the Tomato fungi are in their earlier stages quite superficial, so that if remedies are applied in good time recovery seems to be possible. Experiments with remedies must be made and repeated and reported upon by practical growers. Many recipes and suggestions have been printed of late in the *Journal of Horticulture*.—WORTHINGTON G. SMITH, *Dunstable*.

EVENTS OF THE WEEK.—There are no special horticultural events on record for this week, but the usual auction sales will be held of Orchids and bulbs at Cheapside and King Street, Covent Garden. The Royal Society meets to-day (Thursday) at 4.30 P.M., the Quekett Club on Friday, at 8 P.M., and the Society of Arts on Wednesday, February 19th, at 8 P.M.

— AT the annual general meeting of the ROYAL HORTICULTURAL SOCIETY, held on February 11th, Sir Trevor Lawrence, Bart., M.P. President, in the chair, the following ladies and gentlemen were elected Fellows of the Society—viz., R. W. G. Baker, W. Balchin, Thos. Bate, Thos. Bate, F.S.I., the Countess of Bective, Samuel Bennett, J. H. Wright Bishop, the Rev. Canon Bliss, A. H. Bond, A. T. Bourke, F. A. Browne, Jas. Brown, Miss G. Carter, Miss Ellen M. Chute, Alex. Crossman, C. W. Dalbiac, B. W. Duffield, Rev. W. Elwin, Mrs. Fleming, W. Garton, A. H. Griffiths, J. C. Grinling, W. Hibberdine, Mrs. Hollowell, Mrs. H. T. Lambert, Miss Marie Lowe, Jas. Marson, S. W. Marten, R. W. T. Morris, Lady Musgrave, Alex. Overend, E. H. Oxenham, F. C. Paule, J. W. Pimblett, J. Prestwick, W. Ransom, Mrs. W. Rivington, G. H. Sage, H. E. Simonds, Henry Sowter, Rev. J. Tillard, H. W. Underhill, — Wakefield, Alfred Warner, Eustace Wigram, Alfred Wilson, John Wood, Percy T. Wrigley, T. W. Wellington, Captain Jekyll, R. J. Collier.

— THE WEATHER in the Metropolitan district has been colder during the past few days, easterly and north-easterly winds being

accompanied by frosts of 4° to 8°. The days generally have been bright, Saturday, Sunday, and Monday particularly so, and scarcely any rain has fallen.

— WEATHER IN THE NORTH.—The unseasonably mild weather up to the 5th inst. has been followed by five days of welcome frost, ranging from 7° to 10° on the morning of the 9th. Especially dense hoar frost and heavy fogs have occurred, but some days have been beautifully bright. Farmers have been able to push on operations delayed by the previous rainy weather.—B. D., *Perthshire*.

— TURNER MEMORIAL PRIZES.—We are informed that the following prizes are offered by the trustees for the year 1890:—National Tulip Society. Exhibition to be held at Manchester. The date not yet fixed. For six distinct seedling Tulips, three rectified and three breeders—first prize, 30s.; second prize, 20s. For twelve distinct named Tulips, six rectified and six breeders—first prize, £3; second, £2; third, £1. At the Tibshelf Horticultural Society's Exhibition the following prizes are offered for Roses—viz., for twenty-four cut Roses, distinct, amateurs only—first prize, £5; second, £3; third, £2. At the autumn Exhibition of the Royal Horticultural Society, Edinburgh, September 10th and 11th, twenty-four Dahlia blooms, distinct, Show and Fancy varieties—first prize, £5; second, £3; third, £2.

— THE CRYSTAL PALACE SHOWS.—The schedule of the usual series of shows at the Crystal Palace, Sydenham, is issued, and contains liberal provision for plants, flowers, fruit, and vegetables. The first or spring Show is fixed for Saturday, March 29th, when bulbs and forced plants will constitute the chief features. On Saturday, May 10th, the summer Exhibition will be held, forty-six classes being provided, thirty-two open to all exhibitors. Specimen, show, and greenhouse plants, Orchids, Ferns, Pelargoniums, cut flowers, and floral decorations will form the leading features. The National Rose Society's Exhibition has been previously announced for Saturday, July 5th, and only the regulations are inserted. A Fruit Exhibition will take place on Friday and Saturday, September 5th and 6th, the customary substantial prizes being offered for collections of fruit, Grapes, Peaches, Plums, &c. October 9th to 11th are the dates for the hardy fruit Show, when Apples, Pears, and vegetables are largely provided for, while the Chrysanthemum Show is announced for November 7th and 8th, £25 being offered in four prizes for forty-eight cut blooms.

— MESSRS. WM. WOOD & SON, Wood Green, London, N., send us an excellent sample of ORCHID PEAT, of which they say they have a large stock. It is one of the best samples we have seen, and is admirably adapted for Orchid culture.

— GARDENING APPOINTMENT.—Mr. A. Waters, gardener for the past five years to John Eccles, Esq., Farington House, Preston, and formerly foreman at Norris Green Gardens, has been appointed gardener to Captain Hopwood, Hopwood Hall, Middleton, Manchester.

— WE are requested to announce that the International Exhibition of Geographical, Commercial and Industrial Botany and of Microscopy which was to be held at Antwerp this year cannot, owing to unforeseen circumstances, take place in 1890, but will be opened next year.

— MESSRS. JAMES VEITCH & SONS send for our inspection an assortment of Primula blooms, which in size, substance, and diversity—including the purest and richest colours—are distinctly meritorious. In all those respects such Primulas would have been thought impossible only a very few years ago.

— No doubt the CATERPILLAR PLAGUE was brought about in some measure by cutting down old hollow trees throughout the country, destroying the nesting places of tomtits, which feed their young on small caterpillars, and so disturbed the balance of Nature. As a remedy I propose small boxes, flower pots, or cocoa-nut shells with holes just large enough for the tits, or sparrows will take possession. If plenty of these were hung in gardens and orchards, the tits would soon increase. But I fancy I hear someone say, "They eat my Pears." Well, all I can say is, Net them.—J. DEDNAM, *Much Hadham*.

— MR. A. HARDING writes:—"The WEATHER here (near Peterborough), has been mild, with occasional frost and snow: 15° has been the lowest recorded. The Aconites and Snowdrops were unusually early, are now getting over; but on the sunny rockery, Primroses, Violets, Crocuses, Hepaticas, Omphalodes verna, and even Narcissus bulbocodium citrinus is in bloom, with a few other things. American

Wonder Marrow Peas sown in the middle of November on a south border, look as healthy and hardy, 2 inches high, as William I."

— **LETTUCE VEITCH'S GOLDEN QUEEN.**—This will be found an excellent Lettuce for forcing. On January 9th last year we sowed seed of it in 6-inch pots, and placed them on a shelf in a vinery just started. On February 7th they were planted in a frame on a slight hotbed 6 inches apart, and on April 1st we began cutting capital little Lettuces. Perfect Gem treated in the same way, but planted 9 inches apart, was ready April 16th, thus forming a good succession.—J. H. W.

— **AT the ordinary meeting of the ROYAL METEOROLOGICAL SOCIETY,** to be held at 25, Great George Street, Westminster, on Wednesday, the 19th inst., at 7 P.M., the following papers will be read:—"Observations on the Motion of Dust, as Illustrative of the Circulation of the Atmosphere, and of the Development of certain Cloud Forms," by the Hon. Ralph Abercromby, F.R.Met.Soc.; "Cloud Nomenclature," by Capt. D. Wilson-Barker, F.R.Met.Soc.; "An Optical Feature of the Lightning Flash," by Eric S. Bruce, M.A., F.R.Met.Soc. Capt. Wilson-Barker's and Mr. Bruce's papers will be illustrated with lantern slides.

— **BLENHEIM ORANGE TOMATO.**—"J. E. T." writes from Cumberland:—"I have grown this Tomato for two years, and consider it the most deliciously flavoured variety in cultivation. I have tried nearly every advertised variety, and find that there is not one can hold a candle to it for flavour. The plant is robust, and the fruit sets freely." Blenheim Orange is, we believe, the result of a cross obtained between Dedham Favourite and Green Gage in Messrs. Carter & Co.'s experimental grounds at Forest Hill.

— **GAS-HEATING HOUSES.**—Gas being such a convenient means of heating boilers for warming greenhouses, perhaps more particularly for amateurs (but I am not sure even if it is so limited), it has often occurred to me that if an automatic arrangement could be designed by which the tap regulating the supply of gas was controlled by some kind of thermometer, it would be a great boon, as it would prevent the great variation of temperature which so often occurs. It is just possible such a system as I now suggest has been already tried, but I have never seen any notice of anything of the kind. Are any of your readers aware whether or not it has ever been attempted with or without success?—C. S.

— **MR. G. HILTON,** The Gardens, Smithills Hall, Bolton, writes:—"I send you the rainfall for 1889 taken here; I thought it might interest you. You will observe that the total fall is greater than in 1888, although the early part of the summer was drier and warmer than in the previous year. Dry June was followed by a heavy fall in July and following months, which brings up the total. On the whole it was a better summer, and vegetables succeeded much better. The total for each month is given in inches. January 2.25, February 3.22, March 2.89, April 2.37, May 3.74, June 0.64, July 4.51, August 7.89, September 5.52, October 3.64, November 2.37, December 5.43; total for 1889, 44.45. Total for 1888, 40.32. Rain fell on 188 days in 1889.

— **VICTORIOUS POTATO.**—In my notes on new vegetables I mentioned as the best successor to the Ashleaf Potatoes Laxton's No. 1. I have grown this for two seasons and found it a great cropper, fit to dig about ten days after the Ashleaf, floury and of fine flavour when dug. I am much taken with this Potato, and wrote highly of it twelve months ago in the Journal, but I was under the impression that it was an old Potato, as I had not seen it in any list. Mr. Laxton now writes me that it is his new Potato Victorious, so being unknown to many I thought it well that intending purchasers should know how well pleased I am with it as Laxton's No. 1. I may add that I am indebted to Mr. R. Gilbert for sending it and five other varieties to me two years ago, and out of the six Victorious and Bouncer are the only two survivors, for I have discarded the other four.—H. S. EASTY.

— **A CARGO OF CATS.**—There has just arrived from Alexandria at Liverpool, by the steamer "Pharos" (says the *Daily News*), a consignment of nearly 20 tons of cats, numbering 180,000 feline species, taken out of an ancient subterranean cats' cemetery discovered about 100 miles from Cairo by an Egyptian fellah, who accidentally fell into this cats' cemetery, which he found completely filled with cats, every one of which had been separately embalmed and dressed in cloth after the manner of Egyptian mummies, and all laid out in rows. Specimens of these have been taken by Mr. Moore, Curator of the Liverpool Museum, where they can be seen. In ancient times the Egyptian cat was buried with all honours, but those consigned to Messrs. Levington & Co. of

Liverpool, after being purchased in Egypt at £3 13s. 9d. per ton, will be used in this country as manure. The Curator of the Liverpool Museum fixes the date of their interment 2000 years before Christ.

— **THE LATE MR. WILDSMITH.**—It was with deep regret that I read in the columns of the Journal an account of the death of Mr. Wildsmith of Heckfield. My first interview with him was about eighteen months since, when he came for a few days to this establishment for the benefit of his health. He visited me several times on that occasion, and I shall ever remember his genial disposition, kindly remarks, and the sound practical advice he gave to me at that time. My sympathy is with all who are bereaved through his decease.—W. GABBITAS, *Gardener, Hydropathic Establishment, Harrogate.*

— **DRACENA LINDENI.**—This makes a fine exhibition plant, and has great value for general decorative work, being especially useful for single specimens in vases. It is of recent introduction, and does not differ in its growth from the *D. fragrans*, but the broad arching leaves of green are beautifully ornamented with a wide margin of creamy yellow, which gives to the plant a very attractive appearance, and places it in the front rank of variegated plants. It is propagated easily by the usual method of layering or cutting up the canes; but to make good specimens, fit for exhibition purposes, the heads alone must be used, and these with care will make a fine crop of roots in a few weeks without the loss of a single leaf. *D. Massangeana* makes an excellent companion plant for the foregoing, only differing from it in that the variegation runs through the centre of the leaf instead of along the margin.

— **THE WEATHER IN JANUARY.**—January was very mild, excepting the 1st, 2nd, and 3rd, on which days the frost was moderately severe. Strong winds prevailed during the greater part of the month up to the 26th, on the afternoon of which day the wind blew almost a hurricane, accompanied by a heavy downpour of rain. Rain fell on twenty-five days, the heaviest daily fall occurring on the 26th and 27th, on which days 0.32 and 0.31 inch fell respectively. Snow fell on two days, but did not lie long. Highest shade temperature, 56° on the 25th; lowest, 20° on the 2nd; lowest on grass, 19° on the 2nd. Number of days at or below 32°, in shade eleven, on grass nineteen. Barometer very variable; highest reading, 30.55, at 9 P.M. on the 29th; lowest 28.80° at 9 A.M. on the 23rd. Garden spring running twenty-two gallons per minute, January 31st.—J. TUNNINGTON, *Ketton Hall Gardens, Stamford.*

— It is with regret that we announce the death of MR. JAMES MCINTOSH, who for twenty-nine years—up to 1868—served the late Duke of Buccleuch as head gardener at Drumlanrig Castle. He died February 4th at the advanced age of ninety-four. He was born at Abercairny, in Perthshire, where his father was head gardener. He was brother to the late Mr. Charles McIntosh, author of "The Book of the Garden," and James McIntosh went from Archerfield while Charles was at Dalkeith, and it is rather singular that David Thomson went from Archerfield to succeed him while William Thomson, his brother, was at Dalkeith. The subject of our notice has lived retired near Dumfries for the last twenty-two years, and until within the last year took great interest in his garden, and attended to his plants as a recreation. He was of very retiring habits, and never took much part publicly in horticultural matters. During his service at Drumlanrig many important works were carried out, and he was very much respected by the noble family he so long served.

— **FLOWERS FROM LLANDUDNO.**—Recently I received a box of cut flowers, all grown, without the least protection of any kind, in my garden, near Little Orme, Llandudno. They comprise—Snowdrops, about 300 blooms, Winter Aconites, about thirty blooms, sweet-scented Violets, 300 blooms in twelve bunches, Tea-scented Roses, about 100, mostly with young foliage and healthy buds in various stages of development, Mignonette and Wallflowers in plenty, Anemones, five distinct varieties, Pear blossom, two bunches, Stocks, several trusses in various colours, Oxlips and Cowslips, several trusses of each, Primroses and Polyanthus, sixty blooms and trusses, various colours, Seabious, German varieties, forty blooms in fine condition, various colours. These were a great surprise to me, as my plants at Stakchill, from the same seed, were cut down in October. Antirrhinum and a few other odd flowers. I am familiar with the vagaries of the Primula family, such as Auriculas, Primroses, Polyanthus, Oxlips, and Cowslips; but for such a collection, so plentiful in quantity, so fine in condition, and so widely varied in class, to be cut from the open part of one garden in January, is unprecedented

in my experience, and deserves noting. The Tea-scented Roses with their buds and foliage were especially beautiful.—SAMUEL BARLOW, *Stakehill, near Manchester.*

— DEATH OF MR. GEORGE W. YOUNG.—This name will be recognised as that of a recently elected pensioner on the Gardeners' Royal Benevolent Institution—a pension he has not lived to receive. He was a most earnest, competent, and industrious gardener, as expert in growing specimen Heaths and hardwooded plants as in producing high-class Grapes and vegetables. Mr. Young was for several years gardener to the late Viscount Barrington at Beckett House, Berks, and subsequently became gardener to the late Duke of Buckingham at Stowe. While at Beckett he perhaps grew the fickle but beautiful *Lisianthus Russellianus* better than it has been seen elsewhere, some of his specimens bearing from 500 to 700 handsome blooms. After leaving Stowe he went into business, but lost rather than gained by the change, and eventually returned to work in nurseries and gardens. His zeal and cultural ability appear to be inherited by his sons, three of whom are head and two under gardeners. Of the former, Mr. Arthur Young is gardener to W. Jones, Esq., Abberley Hall, Stourport; Mr. William Young gardener to Captain Winthrop, Barton Court, Berks; and Mr. Henry Young gardener to Captain Fisher, Ingerwood, St. Lawrence, Isle of Wight. Of these sons it may be remarked that three of them are subscribers to the Gardeners' Royal Benevolent Institution, and the other two have taken steps to follow their good example. Mr. Young died on the 4th inst. in his sixty-third year, and was interred in the old parish churchyard at Fulham on Monday last.

— WE are requested to insert the following note:—"A Society of FRENCH GARDENERS in England was some time ago formed, with the object of establishing cordial relations between the gardeners in France and their English *confrères*. The results obtained up to the present are highly satisfactory. Believing that many English gardeners are desirous of sending their sons to the Continent to learn different modes of culture, &c., while we know that many French nurserymen and gardeners are equally desirous of sending their sons to England, we decided in our last meeting to proceed by way of exchange. The Society would thus undertake to place in France an English young man, provided that someone would take in exchange a young Frenchman. The office of the Society is 27, Gerrard Street, Shaftesbury Avenue, where all communications should be addressed." [This Society is worthy of the attention of young British gardeners who desire to obtain Continental experience.]

— THE WEATHER IN JANUARY.—Mr. J. Mallender sends the following summary of meteorological observations at Hodsock Priory, Workop, Notts, for January, 1890.—Mean temperature of the month, 42.0°. Maximum on the 6th, 56.4°. Minimum on the 2nd, 21.0°. Maximum in sun on the 25th, 96.1°. Minimum on grass on the 2nd, 18.1°. Mean temperature of the air at 9 A.M., 40.3°. Mean temperature of the soil 1 foot deep, 39.7°. Number of nights below 32°, in shade seven, on grass eighteen. Total duration of sunshine, forty-seven hours, or 19 per cent. of possible duration. We had eleven sunless days. Total rainfall, 2.44 inches. Rain fell on twenty days. Average velocity of wind, 15.6 miles per hour; velocity exceeded 400 miles on thirteen days, and fell short of 100 miles on two days. Approximate averages for January:—Mean temperature, 37.5°; sunshine, thirty-five hours; rainfall, 1.71. A very mild and stormy month, only two falls of snow and they soon melted.

— THE KEI APPLE, *ABERIA CAFFRA*.—An Australian paper has the following note:—"As many Mildura settlers have at different times made inquiries as to the value of the Kei Apple as a hedge plant, this account may be of use: The Kei Apple is a large shrub or small tree, furnished with strong, straight, long spines, and rather small obovate leaves. The fruit is round, 1 inch or more in diameter, lemon coloured, of an agreeable sub-acid flavour, considered by some to be a desirable fruit for preserves; in an unripe state it is used for pickling. For preserves the ripe fruit is recommended to be used in combination with Pumpkin or Pie Melon, giving an agreeable acidulous piquancy. The plant is one well suited for hedges, for which purpose it must be raised from seed, as it does not strike readily from cuttings. Baron von Mueller says the plant resists severe drought, but bears only a light degree of frost."

— CABBAGE PLANTS CLUBBING.—Most gardeners have had to deal with clubbing in the cultivation of the Brassica family, so for the benefit of those who have not yet found a remedy I give a few

hints as to a method which I have found very efficacious. The ground being deeply trenched and liberally manured, I make the drills and place in 3 or 4 inches of wood ashes (obtained by burning all the hedge clippings, &c.), and then replace the soil. The plants are then put in with a dibble 2 feet apart. After they have started into growth I apply to each a small handful of the Manchester manure, which I find to be very stimulating to vegetables, I also make it a practice to run the hoc amongst them weekly. I have used quicklime and also gas-lime, but not with such good results as those obtained from the ashes. I use the ashes as much for their fertilising qualities as for the prevention of club root, but quicklime has hardly any fertilising qualities that I am aware of. Since following the foregoing method I have not been troubled with club root.—W. J. B.

— BIRMINGHAM GARDENERS' ASSOCIATION.—At the fortnightly meeting held on February 4th, Mr. Henry Deverill, Banbury, sent some of his newer varieties of Onions, which were much admired. Mr. Burdon, gardener, Moseley, sent a collection of Potatoes of high-class quality, amongst them some of Messrs. Sutton's seedlings sent to him for trial, and some of their newer varieties—viz., a very fine seedling white kidney, Sutton's Prizetaker, Abundance, and Satisfaction; and their Seedling 152, a very promising first-class variety. Amongst round varieties were Sutton's Best of All, and their Seedling 151, a very promising flat round; and Sutton's Nonsuch, very fine. The Dean and Woodstock Kidney, with other sorts, were in good character. Mr. Gardiner, Harborne, sent about forty kinds of English and American Apples. Mr. Latham, the Botanic Gardens, showed Camellias and flowers of a South African greenhouse shrub, *Toxicophlœa spectabilis*. Mr. Cooper, The Gardens, Highbury, sent handsome specimens of *Cyclamens Veitch's Charming Bride*, *atrosanguineum*, of a rich dark colour, and a seedling feathered form pure white, distinct and novel. Mr. F. Denning, florist, contributed some fine white *Cyclamens*; and Messrs. Hewett & Co., nurserymen, some excellent forced *Narcissus*, General Gordon, Maximus, and Henry Irving; and selected blue and rich dark red *Primulas*, both very fine in character.

— In reference to the request on page 46 of your Journal, No. 2155, dated 16th January last, I give you, although somewhat late, a list of the French works on the MANUFACTURE OF SUGAR FROM BEET, writes M. E. Schaettel. "*Traité Théorique et Pratique de la Fabrication du Sucre, Guide du Chimiste-fabricant.*" Par Horsin-Déon, price 25 francs. "*La Fabrication du Sucre.*" Par H. Pellet et G. Sancier, price 10 francs. "*Traité Théorique et Pratique de la Fabrication du Sucre.*" Two vols. in 8vo. Par Maumené, price 55 francs. "*Traité Complet de Fabrication et Raffinage du Sucre de Betterave.*" Par L. Walkhoff, translated by Méryot et Gay-Lussac. Two vols. Price 20 francs. "*Guide Pratique du Fabricant de Sucre.*" Three vols. in 8vo. Par Basset, price 30 francs. "*Guide Pratique des Fabricants de Sucre.*" Par Leurs, price 7 francs. "*Guide du Fabricant de Sucre Indigène, Contenant l'Extraction et l'Epuraison du Jus de Betterave.*" Par Possoz, price 4 francs 50 cents. "*Manuel Pratique de la Fabrication et du Raffinage du Sucre de Betterave.*" Par Gautier, price 3 francs. "*Progrès Accomplis dans la Culture de la Betterave et dans la Fabrication du Sucre.*" Par Leplay. First part, 1884-1887, price 2 francs 50 cents; second part, 1887-1888, price 1 franc 50 cents. These books may be had at the office of the "Sucrerie Indigène," 10, rue de Louviers, Paris. Messrs. Vilmorin-Andrieux & Co. have just issued a small interesting pamphlet on sugar Beet seeds, which may be had, free of charge, by applying to the firm.

— THE "Botanical Magazine" for January contains coloured plates and descriptions of several plants, but one deserves special attention—viz., *HELIAMPHORA NUTANS*. This is one of the *Sarracenia* family, a native of British Guiana, and related to *Darlingtonia* and *Sarracenia* in a somewhat interesting manner. Sir Joseph Hooker says—"Viewing the relations between these three genera to one another, the question naturally arises whether to regard *Heliamphora* as a degraded or as an ancestral member of the order. I incline to the latter view, though it points to the surmise that the order originated in a region now separated by upwards of 2000 miles from that inhabited by any of its other members, in so far as their distribution is known. Possibly, not probably, other *Sarraceniaceæ* may exist in the little known mountain regions of Venezuela, though such may not be expected to occur in the volcanic areas of Central America and the West Indies. It remains to add that *Heliamphora* was first re-found by Burke, an English Orchid collector, in the Roraima district in 1881, who brought plants of it to Messrs. Veitch & Sons; and that in 1884 Mr. im Thurn collected it on the occasion of his reaching the supposed inaccessible

summit of Roraima. In his account of the botanical collections which he made during that expedition (Trans. Linn. Soc. Ser. 2, ii. 263), he mentions *Heliamphora* as growing 'in wide spreading very dense tufts in the very wettest places, where the grass happens not to be long. The red-veined pitchers, its delicate white flowers raised high on red-tinted stems, its sturdy habit of growth, make it a pretty little picture wher-

comfortable position to an exposed one where a stone wall would hardly be weather-proof, yet I know of a very handsome pair of *Araucaria imbricata* that have been transplanted and doing well up in the Derbyshire hills, and I would rather risk this than see fine specimens cut and mutilated into disfigurement because they have overgrown the positions they were originally intended to fill instead of being removed to more roomy quarters. But the question may arise as to how these ponderous

FIG. 22.—TREE-MOVING MACHINE.

ever it grows. But it attains its full size and best development, not down in the swamp, but up on the ledges of the cliff of Roraima, and even on the top (about 8000 feet).'' The pitchers, which are exactly like leaves with the outer edges folded in and connected, are green on the outer surface, with reddish spots and markings, the inner surface being reddish brown.

TRANSPLANTING LARGE TREES.

A FEW large trees and shrubs are indispensable in making a new or altering an old place. An astonishing effect can be produced with them that could not otherwise be produced in a lifetime. They not only add antiquity to the scenery, but comfort to the surroundings. Unsightly objects can be quickly and effectively hidden with a screen of large trees, thus transferring the objectionable into the beautiful. Although I do not advocate the practice of taking a delicate tree from a sheltered

living giants are to be successfully shifted. There are many contrivances intended for the above purpose, but I know none so good as the simple machine invented by Mr. Barron of Elvaston, fig. 22. This was first used here about the year 1830, and has been in constant use ever since with the greatest success. The inventor of it writes:— "In the year 1831 I transplanted a Cedar of Lebanon 43 feet high and 48 feet in diameter of branches. The stem of this Cedar, which at that time was 2 feet in diameter, is now more than 10 feet in circumference and a picture of health and vigour. A tree 72 feet high was moved more than two miles in an upright position. Yews from six to eight hundred years old have been successfully moved long distances. Oaks and Larches from 40 to 50 feet high have been moved in the middle of summer without losing a leaf. Large Spruce and Silver Firs on the limestone formation have made shoots 18 inches in length the second year after removal."

It may not be out of place to mention here a famous old Yew near Dover that was successfully moved a few years ago by this veteran tree

shifter. Although some hundreds of years old it has made more growth since it was moved than it did for some years previous. I will now endeavour to write a brief description of the working of these simple machines that may be a sufficient guide to enable the ordinary intelligent novice to use them efficiently. I will take for example a tree of 8 or 10 tons. First mark out a square shaped space about 8 by 10 feet, dig out the ends first to a depth of 2 feet 6 inches, then burrow right under the centre of the tree for the purpose of inserting a strong centre plank capable of carrying the whole tree, when this is inserted under the bole of the tree with about a foot projecting out each end for the purpose of hooking the looped end of the winding rope on. The sides may next be dug out and the end planks inserted under the bole across the centre for the purpose of carrying the side planks which are the next to be fixed. These planks should be 6 inches longer than the mass to allow corner chains to be fastened. These prevent the tree swaying while being conveyed to its future position. If the tree has a long journey or the soil of a loose nature the sides will require supporting with straw and boards bound together with ropes similar to a cooper hooping a barrel. Should the tree be very tall guy ropes are needed to hold it in an upright position. These should be fastened to the tree as high as possible at right angles to enable four men to steady it while being moved, or they may be fastened to each corner of the machine, or both may be required in windy weather. The tree will now be ready for the machine, which is taken in two parts. The hind portion may be first put into position ready to receive the side beams, which are attached to the front limber part of the machine. When the machine is put together the tree will be in the centre. Ratchet rollers are placed across the beams, one each side of the tree, and a double rope for winding. When these are in position and the loop end of the rope hooked on the centre plank, winding may be commenced steadily. Strongslings chains with a ring at one end and hook at the other are fastened to the side beam passing under the centre plank and hooked on the other side, and gradually hitched up as the tree is lifted as a safeguard in case the winding gear gives way. When high enough to clear the ground, the chains may be fastened and the rollers slackened a little so that each chain takes an equal bearing. The principal weight is carried by the sling chains and centre plank. The hole must be filled up level and planked over or the machine will be difficult to get over the loose soil. If planks can be laid the whole distance, and horses cannot be used, men can move an immense weight, or pulleys can be brought into requisition. A square hole with the ends made slanting for the wheels to pass down may be dug with a furrow at the bottom for the centre plank to rest in, to prevent it getting fastened when the tree is lowered into its position.

The machine has to be taken to pieces as before when all the planks are removed. The furrow at the bottom must be firmly packed with earth to make a solid, flat foundation for the tree to rest on. When all is filled in the whole may be thoroughly soaked with water if necessary, and a lofty tree will require supporting with guy ropes or wire—especially in exposed positions—until fresh roots are made and the soil gets solid. It is a good plan to mulch fresh planted trees; it is much better than using too much water. There are several different sized machines, which may be hired of Mr. Barron, Borrowash Nurseries, at moderate cost, with both experienced men and the requisite appliances, or I believe machines are made to order and sold by that firm.—J. H. GOODACRE.

GLOXINIAS.

THESE easily grown plants have been so greatly improved of late years, both in form and colour, that a packet of seed from a good strain may be relied upon to produce superior varieties. Although natives of tropical America, they may be grown to perfection without subjecting them to a high temperature, and although usually found in the stove they can be grown in an ordinary greenhouse, provided they are carefully watered and shaded with due ventilation, but they must be sheltered from draught, as nothing seems to have a more baneful effect upon them than direct currents of air. The best Gloxinias I have seen were grown by an amateur friend of mine on a shelf placed in the apex of his span-roof greenhouse. He had plenty of plants in 6-inch pots last year carrying between thirty and forty splendid blooms and as many buds at the same time, and the plants, with their large healthy leaves, were pictures in themselves without the flowers. This amateur took the Gloxinia in hand three years ago, and has each year produced examples that has taken the conceit out of at least one gardener. He pots his plants into three-fourths sandy loam, the other part is made up of peat, sand, and charcoal; but this is not a compost I should feel safe in recommending the tyro, for I believe very few would succeed with it. Of course the plants will not grow so fast in a greenhouse, but their leaves are of great substance and their flowers very durable.

The seeds of Gloxinias are extremely small, and great care is necessary in sowing them. The pots or pans should be well drained and filled within one inch of the top with equal parts peat, sand, and cocoanut fibre, and this compost should be thoroughly mixed by passing it several times through a half-inch sieve. Press it into the pots moderately firm, and make the surface level by shaking a little of the soil through a very fine hair sieve, after which give a good watering through a fine rose. In about two hours the pots will be ready for the seed, which should be sown regularly and thinly, and a very little soil shaken through the hair sieve to cover the seed, but care must be taken not to bury it deeply. The seeds will germinate in a temperature of 60°, but

if the pots can be plunged in a bottom heat of 70° it will hasten germination. Place a pane of glass over the pot, also a little moss over the glass, until the seed germinates, when it should be removed and the seedlings gradually exposed to more light and air, but no direct sunshine.

If the soil in the seed pots becomes dry it must not be watered in the ordinary way, or three parts of the plants may be lost, but stand the pots in warm water not quite deep enough to rise through the soil to the surface. Let no anxious beginner disregard these apparently trivial matters, for much good seed is lost every year and condemned as worthless through careless or improper management, and as a consequence many a honest seedsman has been branded with a bad name. The greatest care, patience, and skill are required with the young plants, and trivial neglect, that would be unnoticed at a later stage, may prove fatal here. Place other pots of soil prepared as advised for the seed into the same house to warm, and when the seedlings have two leaves prick them off singly, or if they have come up thickly in bunches about 1 inch apart. This is always a delicate operation, and necessitates having the soil on the surface very fine and level. Do not attempt to lift them with the fingers, but first make a dent in the soil of the pan, and with a stick or cedar pencil transfer a plant or bunch of plants into the dent, and carefully press the fine soil round it. When all is complete give a sprinkling of warm water through a fine rose, and place a pane of glass over the pan until the plants start into growth again. As soon as the leaves touch each other prick the plants off again about 3 inches apart into pans or boxes. All those pricked off in bunches should be carefully separated, and the plants may be sorted in sizes, some of which may be large enough to place into thumb pots; but we find them succeed best in pans or boxes until they have grown into large plants—indeed, unless wanted in pots they may be flowered in boxes the first year. For greenhouses and staged conservatories they are undoubtedly most useful in pots; hence before becoming crowded they should be placed into pots, ranging from 3 inches to 5 inches according to the size of the plants, using a compost of peat, leaf mould, light sandy loam, and sand in equal parts, with a sprinkling of powdered charcoal and bonemeal. The pots must be well drained, and the soil pressed in moderately firm. Sudden checks should be carefully avoided, or it may induce them to throw up a few flowers before the plants have attained any size, but after each shift they should be kept close and warm until they take to the new soil, after which give them more air and plenty of light, but always shade from direct sunshine. Watering must be carefully attended to, as if Gloxinias become dry or too wet the leaves may turn rusty, and the plants be stunted. When they get into this unsatisfactory condition they are seldom any good until rested and repotted.

Some fine varieties are sure to appear amongst seedlings from a good strain, and these the grower will be anxious to increase. Gloxinias are easily propagated, and if the stock plants can be placed in a strong moist temperature a large quantity can soon be worked up. Spread a layer of fibre or half-decayed leaves over the bottom of boxes or pans, then pack the bulbs closely together and cover them level with the crowns with equal parts fibre and sand. Place them in a temperature not less than 70° in a somewhat subdued light, the object being to produce cuttings by elongating the growths instead of forming short-necked crowns, as they would do if given plenty of light and room. When growths with three joints are produced cuttings should be taken immediately below the second joint, thus leaving one joint on the stock plants for the production of future cuttings. Dibble the cuttings into well drained pans, using fibre and sand in equal parts, with a layer of sand on the surface. Bottom heat will facilitate the rooting, but it is by no means essential, as if placed in a temperature of 70° they will root in a fortnight. If wanted for growing into flowering plants treat them as soon as rooted the same as advised for seedlings, but if more cuttings are required treat them as the stock plants. In this way a large quantity may be worked up from a very limited stock. Those who have not sufficient heat and convenient places at command must resort to the slower process of increasing their stock by leaves. Cut off a few of the oldest leaves with about half an inch of the petiole attached and insert them round the edges of 6-inch pots, burying about half an inch of the blade, when in time a bulb will form at the extremity of the petiole. A more economical way with large leaves is to make incisions about half an inch apart along the primary vein, then firmly peg the back of the leaf to the soil. Leaves treated thus should not be kept too wet or close, or they may decay before bulbs are formed. If properly managed, however, bulbs will form at every incision, and these, after the leaves have decayed, should be gathered from the soil and stored in dry sand for another year in a temperature not lower than 55°.—J. H. W.

BOUVARDIAS.

MUCH of Mr. Bardney's advice on Bouvardia culture, page 12, is sound and reliable; yet those who have grown large quantities of these plants may question the wisdom of some of the treatment advised. For instance, he says, "It is a good plan to adopt a two-years system of raising plants," and he advocates the practice of crowding a number in a box for a season, for no other reason than to obtain a stock for the following year. Unless space is so very limited that an early start is impracticable, I question the utility of this for two reasons—viz., waste of time and opportunity, and because fine plants can be grown and flowered the same season from cuttings struck in March, with very little coddling either.

Again I cannot see the wisdom of such close pinching as he recommends—"after each pair of leaves." The plants may be kept very close and stocky by that system, but he must pinch the very life out of them also. In growing Bouvardias I want large trusses of well developed flowers borne on stout stems. Let Mr. Bardney run up a few without stopping until they attain a height of 18 inches, which early struck cuttings are not long in doing, then stop at every second or third pair of leaves until the end of July, generously treating the while, and he will have fine plants, rather spreading perhaps, but the quality and quantity of the bloom, and the main stems as thick as a lead pencil, will probably astonish him.

The size of the pots mentioned—4½ inch—does not speak well for the corresponding size of his plants. Grown well 7 and 8-inch pots are filled with roots long before blooming time, but not if placed out of doors—another detail open to debate. A week's wet weather plays havoc with their delicate feeders. Cool, airy houses or cold frames are best in my opinion for summer accommodation. With plenty of air and sunshine strength is not obtained at the expense of solidity. No one, however, should be in a hurry to remove them from warm quarters until they are well advanced in growth.—S. Y.

ROYAL HORTICULTURAL SOCIETY.

REPORT OF THE COUNCIL FOR THE YEAR 1889.

THE work of the Royal Horticultural Society cannot be said to have stood still during the year 1889. Three most useful Conferences have taken place at Chiswick—viz., on Roses, on July 2nd and 3rd; on Vegetables, on September 24th 25th, and 26th; and on Chrysanthemums, on November 5th and 6th; and the excellent results thus obtained, together with the most valuable statistics and returns sent in by the kindness of correspondents all over the United Kingdom, with a few from foreign horticulturists, will, as recorded in the "Society's Journal," form an authoritative standard of reference on the subjects concerned for some years to come.

Sixteen fruit and floral meetings have been held in the Drill Hall, every one of which has been productive of good results to one or other of the different branches of practical horticulture. The number of awards has been as follows:—On the recommendation of the Floral Committee fifty-four first-class certificates, eighty-four awards of merit, four botanical certificates, three commendations. On the recommendation of the Fruit and Vegetable Committee seven first-class certificates, three awards of merit. On the recommendation of the Orchid Committee twenty-seven first-class certificates, seven awards of merit, and twelve botanical certificates.

The Society's great Show, held (by the renewed kindness of the Treasurer and Benchers) in the Inner Temple Gardens, was even more magnificent than in the preceding year, the collection of Orchids in particular having probably surpassed any collection ever before gathered into one place. The best thanks of the Society are due to all those (and especially to the amateurs) who so generously lent their plants for exhibition.

Nor has the Scientific Committee been idle, and the notes of their meetings, as given in the Society's Journal, will be found full of interesting and valuable information to all horticulturists.

Meantime, the Society's general work of scientific experiment and investigation, and of the practical trial of various plants, has been going on steadily at Chiswick under the superintendence of Mr. Barron. Trial has been made of 104 varieties of Potatoes, 50 vars. of Broccoli, 108 vars. of Vegetable Marrows, Pumpkins, and Gourds; 30 vars. of Onions, 30 vars. of Brussels Sprouts, and 41 vars. of Peas. Amongst flowers trial has been made of 270 varieties of garden annuals, 66 vars. of China Asters, 20 vars. of Stocks, 190 vars. of Dahlias, besides Zonal and other Pelargoniums; Lemoine's New Hybrid Gladioli, Pentstemons, Heliotropes, Iris, &c. Ivies, of which the Society possesses a very fine collection, have been specially examined and classified. Reports on these trials will appear in the Journal. Of Chrysanthemums, 800 varieties were grown, and these not only added very materially to the display at the Chrysanthemum Centenary Conference, but from not being so severely disbudded, as is usually the case in producing the show blooms, the plants themselves, as well as the blossoms, were greatly admired. A large sum of money has this year been spent on the gardens. Extensive repairs have been done to the glass houses, and the general keeping up of the gardens greatly improved. The breaking down of two of the largest boilers threatened a great addition to outlay, but the liberal gift from Messrs. Foster & Pearson of one of their patent Chilwell boilers greatly reduced the expenditure under this head. A new hybrid Tomato, considered to be one of the best in cultivation, has been raised by Mr. Barron, and the seed distributed amongst the Fellows. The experiment of opening the gardens on Sunday has not met with such success as the Council had hoped, but they have decided to continue it—at least, for the present year; and then, if the privilege should not prove to be more highly valued, it may have to be abandoned, as, besides the additional work thrown on the officers on their one rest day in the week, it also entails considerable expense on the Society. The meetings held at Chiswick during the year, though successful in all else, have not been quite so successful in point of numbers as the Council had hoped; and they venture to think that in the year now commencing those Fellows who were so strongly in favour of meetings at Chiswick should make it their business by every means in their power, privately or through the Press, to increase the numbers attending.

But perhaps the chief event of the year has been the revival of the Society's Journal, by means of which Fellows at a distance are enabled to enter more fully into and reap the benefits of the study and work of those more actively engaged at the centre. Four volumes, containing about 750 pages, have been issued during the twelvemonth, and the Council have the gratification of knowing, from numerous letters received, that these volumes have been highly appreciated, not only in this country, but by correspondents all over the world.

The invaluable work of 376 pages on "British Apples," which Mr. Barron was able to produce as the outcome of the Apple Conference, 1888, is now being re-issued by the Society in a cheap and popular edition at the price of 1s. 6d. only. It may be as well to point out that unless this issue should command a very large circulation it will entail a great loss to the Society; but the Council have felt, in face of the wide-spreading interest taken in British fruit culture, and of the fact that this book is a standard work upon Apples, that it was their duty to encounter this risk, hoping that individual Fellows would endeavour to promote its sale amongst their neighbours and friends.

All these Conferences and meetings, and especially the work and maintenance of the Chiswick Gardens and the publication of the Journal, have involved the Society in a very large outlay, and the Council take this opportunity of endeavouring to impress upon Fellows the absolute necessity there is for them all individually (as many as have the Society's welfare at heart) to endeavour to secure new Fellows to the Society if its work is not only to be continued at its present standard, but still more so if the ever-opening and extending opportunities of usefulness are to be embraced and accepted. The adoption of £1 ls. as one rate of subscription was, no doubt, a popular movement, but the Council desire to remind the Fellows that such a low rate of Fellowship can only be self-supporting if it draws into the Society a very large number (far larger than at present exists) of additional Fellows. The Council, therefore, venture to express the hope that every Fellow of the Society will make an endeavour to obtain at least one new Fellow during this present year. A statement of the privileges of Fellows and of the aims and objects of the Society, together with a form of nomination to Fellowship, is for this purpose enclosed with this report.

The revival of lectures at the afternoon meetings has been another good feature in the year's work, and the Council hope that as the fact of these lectures and their value become more generally known, through their publication in the Journal, that the attendance of Fellows to hear them, and to take part in the discussions, will gradually increase. The Council cannot but think that many of the Fellows are unaware of the immense interest and value of these regular bi-monthly meetings and the lectures so kindly delivered thereat; and they beg to express, in their own name and in that of all Fellows of the Society, their very best thanks to all those gentlemen who have so kindly contributed, either by the exhibition of plants, fruits, flowers, or vegetables, or by the reading of papers, to the success of these meetings.

The papers read at these bi-monthly meetings, all of which have been published in the Journal, are as follows:—

The hearty thanks of the Society are due to the Chiswick Board and to all the members of the standing Committees—viz., the Scientific, the Fruit and Vegetable, the Floral, the Orchid, and the Narcissus Committees—for the most kind and patient attention which they have severally given to their departments; to the exhibitors and members of the special Committees also, who have contributed to so great an extent to produce the magnificent results of the Rose, Vegetable, and Chrysanthemum Conferences. And herein the Council cannot refrain from thanking especially the Very Rev. the Dean of Rochester, Mr. Harry J. Veitch, Mr. Shirley Hibberd, Mr. Molyneux, and Mr. Mawley, together with all the officers of the National Rose Society, who so cordially, and with such kindly feeling, co-operated in the Society's labours.

In conjunction with the Lindley Library Trustees the Society's library has received considerable attention. Several defective series (notably the *Botanical Magazine*, now complete from its commencement) have been made good up to date, and a large number of untidy but valuable volumes have been bound.

The best thanks of the Society are due to all those who, either at home or abroad, have so kindly and liberally presented books to the library or plants or seeds to the gardens. Special thanks are due to those gentlemen who have so kindly contributed Carnations in view of the Conference in July. A list of the donors has been prepared, and will appear in the next number of the Journal.

The Council recognise as fully as anyone can the great desirability of securing more suitable premises than the present Drill Hall affords, and they are now anxiously engaged in considering a scheme for erecting a suitable building on the Thames Embankment, which, if ever accomplished, would, they hope, not only afford ample facilities for our own Society, but also, in time, form a centre for all kindred horticultural associations. But they must remind Fellows that the adoption of this scheme is purely a matter of funds, and would entail a very large outlay, and until they can see their way to provide this they fear that no better place than the Drill Hall can, under the circumstances, be readily found.

The Council have the sad duty of recording the death of forty of the Fellows of the Society during the past year. Amongst them they regret to find the names Reichenbach, Boscawen, and Berkeley.

Besides the losses from death the Council deeply grieve to have to record the loss of thirty-nine Fellows by resignation. The Society has been struggling bravely for the last two years in the face of many adverse circumstances, and with the burden, financially speaking, of a large number of life Fellows—from whom it derives no income whatever—bequeathed to it by a former generation; and the Council had hoped that, with the evidence which even this report gives of renewed life and vigour and usefulness, the Society would have retained the goodwill and support, and for a time the forbearance of all who had joined it. They have, however, the pleasure of adding that a greater number have joined the Society than have left it. Still, as they said in another paragraph, they wish to impress very strongly the fact that the Society needs a large augmentation before it will be financially possible to embrace the many opportunities of usefulness opening before it. The following tabular statement will show the relations of increase and decrease during the year, both in the number of Fellows and the income arising therefrom:—

DEATHS IN 1889.				FELLOWS ELECTED IN 1889.

LUPINUS ARBOREUS.

I WAS very pleased to see this border plant spoken so well of by Mr. S. Arnott on page 92. It well deserves all the praise there accorded it. I have found it one of the best plants for cutting purposes in June, July, and August. From a plant 5 to 6 feet in height I have twice a week cut large handfuls for those three months, and anyone having to provide a mixed supply of flowers would do well to purchase seed this spring. It should be sown as soon as possible, and the seedlings planted out in a sunny position at the end of May, hardening them off in the same way as a bedding plant. Eight years ago I purchased from a well-known London seed firm a packet of seed, and the following year and ever since I have had plants for cutting from in the above named months. Only one plant was then placed out, and the flowers proved a bright yellow colour. The foliage, like most of the Lupins, is bright

and elegant, and stalks with flowers and foliage attached can be cut a foot in length. This one plant died last spring, but in the autumn previous three cuttings were taken, placed in a 60-pot in a cold frame, and luckily one of these struck, and is now a plant 2 feet in height with a stem 1 inch in diameter. It has survived the winter so far, and if it lives will prove a useful plant for the future. I attribute the death of the older plant to late spring frosts. It starts into growth rather early if it happens to be at all mild in the month of February. The position chosen was a mixed herbaceous border sheltered from north winds, where it grew 6 feet high without any support, and had a main stem near the ground 5 inches in diameter.

I cannot enlighten Mr. S. Arnott on the short duration of this Tree Lupin, but it would be more safe to perpetuate it occasionally by cuttings or seeds. It certainly is worth a little trouble, for it is of far more beauty and usefulness than many of the bedding plants that require annual raising. In hardiness it has withstood 15° and 20° of frost on several occasions, but, as stated above, it has a habit of starting to grow rather early in spring. A space 6 feet by 6 should be allowed it. According to Don's "*Hortus Cantabrigiensis*," this species is a native of California, and was introduced in the end of the last century.—A. HARDING.

THE FINANCIAL SUCCESS OF CHRYSANTHEMUM EXHIBITIONS.

(Continued from page 112.)

To the Scottish Horticultural Association must be left the honour of surpassing all other societies last year, both in point of numbers in the attendance, and the amount taken at the doors. In justice to other societies it must be mentioned that this Society were celebrating the Centenary Exhibition of the Chrysanthemum, for which special attractions were provided. A large Chrysanthemum Show in Edinburgh was more of a novelty than anywhere in England, and no doubt added considerably to the attractions of the whole. Nowhere in existence is there such a fine site as that possessed by this Society. In spite of the advantages here named, much credit is due to all concerned for the way in which everything was managed concerning a very successful Exhibition. Although Edinburgh has not more than a population of 262,733, the amount of visitors was 31,945 during the three days which the Show was held, and which paid for admission. In addition to these, the Committee gave free admission to nearly all the charity schools in the city, the employes in the various nurseries, and gardeners in the City Garden, as well as to the employes in the municipal and Police Offices, and many soldiers in the Castle and the Barracks, beside 1000 tickets to guarantors and subscribers, making in all fully 3000 free passes, which brings the grand total of visitors up to 35,000, truly a remarkable number, exceeding even Portsmouth by over 13,000. The takings at the doors exemplify the wisdom of popular prices strongly. From 1 to 10 P.M. on the first day £425 3s. was realised; from 11 A.M. to 5 P.M. on the second day at 1s. charge £168 18s., while from 5 P.M. to 10 P.M. at a 6d. charge reached the large sum of £197 14s., making a total for the day of £366 12s. On the third day at 1s. and 6d. entrances £384 11s. 3d. was realised, which amounts in a gross total to £1176 6s. 3d.—truly a remarkable sum. Upon the first day very large numbers of ladies were present, who appeared to criticise and admire the exhibits in quite a hearty manner. In a summarised manner I give the total gate receipts of each place:—Portsmouth, £240 5s. 5d.; Birmingham, £277; York, £171 10s.; Hull, £241 2s. 6d.; Edinburgh, £1176 6s. 3d.—E. MOLYNEUX.

In Mr. Molyneux's excellent article on this subject, in the Journal of 6th February, I observe he is under a slight misapprehension as to the price of admission at the Hull Society's Show, as the time from 12.30 to 3 P.M. on the first day is the private view open only to members and holders of members' tickets, members having the privilege of obtaining tickets in excess of the number to which their subscriptions entitle them, at 2s. 6d. each on production of their passes at the door. No other money is taken until three o'clock, but the members and their friends are so numerous, that the rooms are always well filled at the opening ceremony at 12.30. I believe few shows open so early as this on the first day, even to members.—R. FALCONER JAMESON, *Chairman Hull and East Riding Chrysanthemum Society*.

THE TEDDINGTON CHRYSANTHEMUM SOCIETY.

THE annual general meeting of this Society was held at the Public Schools on Friday evening. There was a fair attendance of members. Mr. J. J. Staples was voted to the chair. The accounts, as audited, were presented by Mr. Furze, the Treasurer, showing a balance of £16 in hand, including the £10 in reserve fund. The accounts were passed, and a vote of thanks was accorded Mr. Furze for his valuable labours on behalf of the Society. Mr. F. Braby was re-elected President, and all the Vice-Presidents, with the exception of Mr. Binder, who has left the neighbourhood, were re-elected. The following were added—Col. Paske.

Messrs. D. Ames, W. Howard, J. J. Staples, W. F. M. King, and E. A. Burchell. The Treasurer, Mr. W. Furze; the Secretary, Mr. D. Anderson; the Auditors, Messrs. W. Millwood and R. S. Walker, were re-elected, and thanked by vote for their services, similar compliment being paid to the collectors, Messrs. W. Davies and W. Neave, who are appointed by the Committee. It was resolved that the next show be held at the Town Hall on November 13th and 14th, and the Secretary was instructed to inquire if Mr. G. Woodgate, Kingston Hill, and Mr. Lewis Castle, Merton, last year's Judges, would again undertake that duty.

LATE CHRYSANTHEMUMS.

By this post I send you two blooms of late-flowering Chrysanthemums. The reflexed Japanese is one of the best of its colour for late blooms. It produces flowers of good size, and the colour is all that is needed. The name is Sunbeam, an American variety. The other is also American variety, H. Waterer. Its fault is that it is rather tall, but very durable, the flowers lasting some weeks in perfection. The most useful of all late varieties is Golden Gem. This variety forms a nice bush plant when stopped until late in July, and gives abundance of apricot and yellow flowers through January and early February.—R. OWEN.

[Sunbeam certainly seems to be a promising variety, but we cannot say so much in favour of the other, judging by its present condition.]

THE LEICESTER AND MIDLAND CHRYSANTHEMUM SOCIETY.

THE annual meeting of this Society was held at the Temperance Hall, Leicester, on the evening of the 29th ult., when there was a good attendance of members and subscribers, Mr. W. K. Woodcock presiding. The report and balance-sheet for the past year was read by the Honorary Secretary, Mr. J. Read, the latter showing that although the expenditure in prizes awarded, hire of rooms, judges' fees, &c., had been greatly in excess of previous years, such additional outlay had been proved to have been judiciously incurred, from the facts that it had been well met by additional subscriptions and greatly increased takings at the doors, and that it had served the useful purpose of giving the Society a much better standing and status in the town and district. The accounts showed that all claims had been duly paid, and that the Society starts on the new year with a small balance in hand.

A letter was read from T. W. Wright, Esq., an ex-Mayor of Leicester, and a gentleman extremely popular in the town and district, accepting the office of President of the Society. The list of Vice-Presidents comprises the names of most of the best known and most influential residents in the town and neighbourhood, including the Marquis of Granby.

The other officers and a Committee were elected for the coming year, which, with a few slight alterations to rules, and votes of thanks to the officers for their work so well done during the past year, terminated the business.

On Wednesday evening, February 5th, the first meeting of the new Committee was held, Mr. W. K. Woodcock again presiding, when the first business upon the agenda was to fix dates for the next show. These were ultimately decided upon, by an almost unanimous vote, as to be the 14th and 15th November. It was also decided that the Temperance Hall be again engaged as the place for holding the same. The Judges selected were—Messrs. Jno. Wright and W. Tunnington. A communication was made to the meeting that one or two of the Vice-Presidents had taken upon themselves to provide a large silver cup to be awarded in the open class for forty-eight cut blooms at the next show. Several members of the Committee also signified their willingness to undertake the collection of funds for the purchase of what shall be termed the Tradesmen's Cup, to be subscribed for by Leicester shopkeepers, and awarded in a new district class to be formed. The further arrangement of the schedule was deferred pending the receipt of fuller information regarding these matters.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

THE annual general meeting of this admirable Institution was held on Monday evening last in a large room of the Caledonian Hotel, Robert Street, Adelphi, London, Mr. J. Wright in the chair. The minutes of the last meeting having been read and signed, the report of the Committee and balance-sheet for the past year were read by the Secretary, and showed that substantial progress was being made. One member had died during the year, and forty were elected. The members' share to the sick disbursements were a little under 3s. each for those subscribing 6d., and a little over that sum for those subscribing 9d. per week, the invested surplus for the members amounting to £400 during the year. The present position of the Society and its character appear to be embodied in the Chairman's address. After referring to the able manner in which Mr. R. Dean presided on many previous occasions, when the Society was comparatively obscure, and the good services he had rendered, and would render again, the Chairman, in moving the adoption of the report, proceeded:—

About seven years ago I made myself better acquainted with this Society than I had before, by a close examination of its books. These were placed before me by its then Secretary, the clear headed and good hearted Mr. McElroy. I was invited to examine every page, scrutinise every item, and point out every fault. I have recently examined the

books again with the present courteous secretary, Mr. Collins, and the more I look into the constitution of the Society and its working over a period of years the more I am satisfied on the following essential points:—

1. Its absolute safety and undoubted stability.
2. Its great excellence and wonderful comprehensiveness.
3. The advantages it offers over general benefit societies.
4. Its careful, economical, and admirable management.

Now given those conditions—and I am thoroughly convinced they are embodied in this Society—then I ask, What more can be expected or desired of a benefit and provident institution?

The "United," to employ a short term well understood, is safe and sound—"safe" because the benefit funds are invested in Government and Corporation stock, and nothing can be safer than that; "sound" because they have from the beginning until now, and without any exception, increased in an enormously greater ratio than the withdrawals for sickness, and this preponderating increase of capital over liabilities must continue so long as the same conditions continue—a steady accession of members and the maintenance of the average health statistics. From these any material departure for the worse is an extremely remote probability; indeed, there is no evidence to justify us in regarding it as a probability at all, for probabilities lie in the other direction—improvement.

We have learnt from the report now presented for adoption, that the past year shows both the prosperity and usefulness of the Society. The experience, however, of any one year does not adequately represent its character; yet if we take what may be called the worst year—the year in which the deductions for sickness were by far the greatest on record, and which may be fairly regarded as abnormal—we find the receipts exceeded the expenditure by no less than £263 13s. 7d. That was in 1887. Passing to 1889 we find the income exceeded the outlay by £421 6s. 8d.; or, in other words, a gain in receipts of £134 7s. 6d., and a reduction in sick disbursements of £43 5s. 7d. over 1887—a very marked improvement on both sides of the ledger. But a fairer test for ascertaining the true position of the Society is to take an average of the last five years, and this shows a yearly addition to the benefit fund of £345 2s. 7d., and an average annual outlay of £32 3s., or a yearly gain for investment during the period of £312 19s. 7d. Multiply this by 5, and we find that the sum acquired in as many years, and placed to the credit of the members, to be no less than £1564 17s. 11d.

Is not that remarkable? I suspect it is unparalleled, and especially when the fact is remembered, for a fact it is, that there is not a farthing of expense as a set off against it, this being met by a small special fund provided by the far-seeing founders of this splendid Institution. Further, when, as we find in the balance sheet, that a sum exceeding £5000 now stands to the credit of the Society, surely not another word is needed on the question of its safety and stability.

Now we pass to the second claim—the great excellence and wonderful comprehensiveness of the Society. One of its excellencies is common to all benefit societies—namely, the right of members to payment during sickness over a prescribed period. When the limit is reached—a year—and a member continues ill, there is a substantial Benevolent fund to grant him further aid, of which he may more than ever be in need. No one knows till occasions unfortunately arrive, what good this wisely established fund may do. It has been of great service under sad circumstances in the past (the last occasion being a grant of £20 to four orphans, who lost both parents in three months), and may be, and probably will be, a perfect Godsend in the future to some poor aged and needy fellow mortals. Ordinary members only contribute one month's annual contribution to the fund, its main support being by contributions of honorary members. Gardeners' Friends who have the means and disposition to do so are thus afforded an opportunity for sharing in the good work of providing against unforeseen calamities, or for affording additional or supplementary relief to the sick payments in cases of emergency. It is most gratifying to note the great increase of honorary contributions during recent years since the character and scope of the Society became better known. When I examined the books seven years ago there were only eight of these, but now there are forty. And it is to be further noted that should misfortune befall any of these members, even they, though honorary, are entitled to assistance from the fund which they have largely created and largely sustain for the benefit of others. We ought to be very proud of the men who formulated rules so comprehensive yet so precise, by which the greatest amount of good can be done and absolute security maintained.

Next to be referred to are the striking advantages the "United" offers over general benefit societies. Here we come to something that stands alone, distinct, and superior to anything that can be found, I believe, in connection with any other benefit society in the world—the investment of the surplus accumulated capital (excluding £1416 14s. 10d. of the Benevolent Fund), now amounting to £3478 18s. 11½d., to the credit of the members. This is theirs, not only without any drawbacks, but with all accumulations, for the yearly interest on each member's share is added to his capital investment, for it is as surely his as if the money passed from his own hands into the Bank of England. Further, the exact amount banked for each member is made known to him every year. The sums are steadily accumulating, last year's increase being £400, and will do so as long as the subscriptions are paid; and even if they lapse the amount invested remains the property of the defaulting member, and is payable to him if he attains the age of sixty years, or at his death, whenever that may occur, to his

nominee, whose name is entered on the books; but, and here is a little penalty which the shrewd authors of this grand scheme imposed. When a member ceases payment—ceases, in fact, to be a member, the interest earned by his share of invested capital is not added to it, but is transferred to the management fund; and at the present moment a sum of £339 16s. 4½d. stands to the credit of persons whose payments have lapsed. They lose the interest on that amount, therefore the Society does not lose by losing a few members, but gains. Still, it is always striving for more. Why? Because it is for their benefit. That is the great central, indeed only possible, object of its existence. No power on earth can deprive a member of one farthing of his investment, and no official has a fraction of pecuniary interest in the increase of those investments. It is said that corporations have no souls, but here we have an exception, for this corporation of gardeners for the benefit of gardeners has 310 souls, for that is the present number of members, and each has an irrefragable claim for a clearly defined share of the accumulated property. He pays his contributions, his share of the disbursements are yearly deducted, and the rest, the great bulk, is placed in the bank for him. Nor has he many years to contribute before nearly the whole of his payments to the benefit fund are added to his accumulated store, for the interest arising from this approaches his yearly contributions to this fund. An example or two will show this clearly.

The first name on the books is that of Mr. W. Heale, but he is dead, so we take the account of Mr. J. George, whose name stands second. His accumulated stock is £59 4s. 5d.; his contributions for the year were £1 19s., while the interest from his stock, and added to it, was £1 12s. 1d., so that as compared with ordinary benefit societies, in which no surplus is invested for the members, he insured himself for 16s. a week in case of illness by a yearly payment of 6s. 11d., or less than 2d. a week; he, of course, paid his 9d. a week, but 7d. of this was added to his invested property. Third on the list of subscribing members stands Mr. J. Wheeler. His invested fund is £39 3s. 7d.; year's contributions, £1 6s.; interest from and added to stock, £1 1s.; difference, 5s. It will be noted that these two members joined at the same time, one paying 9d. a week for 16s. during illness, the other 6d. a week for 10s. 6d. during illness; but the former has £20 more than the latter standing to his credit in the books. Though the advantage of the larger contribution is shown here it does not follow that all young men do best by commencing with the larger payment—on the contrary, experience tends to show that it is better for those with very low wages to commence at the lower scale and pass to the higher when they can better afford to do so, as it is found that a considerable per-centage of those who join on the maximum rate fail to meet their engagements. This is to be regretted, but it is better to state facts than suppress them because they do not happen to be the most agreeable.

Now, all the benefits of this Society, including the substantial personal investments, are insured by smaller annual payments than to general benefit societies, the members of which have no share whatever in the invested reserve funds. Mr. George Baker of Membrand Hall, one of the oldest members of the Society, and I think one of its founders, but certainly for some years its Treasurer, once showed me so forcibly the great advantages of this over such societies as the Odd Fellows, Foresters, and others, that I repeat his words, which I took down at the time, and I should be glad if they could reach the ears of every gardener in the kingdom. "I have paid," he said, "7d. a week into one of those clubs since I was eighteen years of age, and I am now fifty. I have fortunately had nothing out in that time, and if I go on paying all my life there will be £12 at my death." And then he continued, "I have paid 1d. a week less into our Gardeners' Society for seventeen years, and have nearly £40 to my credit, and if I continue paying as long as I paid into the other I shall have £100." This, mark you, is £100 in the "United" against £12 (at death) in the general, and a penny a week more for insuring the £12 than the £100, the benefits during the sickness being practically the same in both cases. Mr. Baker's words should be pondered over by every gardener between eighteen and forty-five years of age, whose ears they may reach, and he will surely take advantage of his position and opportunity in joining this combined benefit society and savings bank in preference to the general societies, which, however valuable they may be to a mixed community of workers, cannot offer anything like the advantages that the "United" does to those for whom it was established.

Before a member of ordinary societies can receive payment during sickness he must relinquish work entirely. This is not so in the "United." He can do some work, and thus keep his situation, and at the same time receive a proportion of sick pay on a doctor's certificate. This is a provision; but as if to help what may be called a half pay man off the fund, there is a slight deduction from his payment, which goes to the benevolent fund. What astute men the framers of these rules must have been, and I think I am safe in saying their equals have not been found outside the gardening ranks. It is the duty of all gardeners to take advantage of their positions and the privileges offered them by this Society, and those of them who have joined the mixed general societies have little to lose and much to gain by having themselves enrolled as members of the "United." Many have done so, and more on reflection must follow their example. I certainly would not suggest their doing this if I were not convinced it would be to their advantage, for a thousand new recruits would not benefit me in the slightest, nor others who are connected with the institution.

The last of the four essentials that have occurred to me as such is the careful, economical, and admirable management of the Society.

There can be no waste of wealth, no fat salaries, no feasting out of the funds; the rules are too stringent for that. Every man who gets a penny out of the Society for services rendered to it must earn twopence at the very least. The secretary's work in keeping three sets of books, making out an annual balance sheet for every member, and writing between 400 and 500 letters is done for £20; the trustees' expenses during the year were 19s. 6d., and treasurer's, 10s. If the work were not a labour of love born of a desire to help their fellow men, the officials could not work so zealously as they do, always have done, and I venture to say always will do; for I am confident there will never be wanting in the gardening ranks bright-minded and large-hearted men who will honestly, earnestly, and gladly do the best they can for the community to which they are proud to belong; and I trust the time is not far distant when the cream of that community will be united under the banner of the United Horticultural, Benefit, and Provident Society, the twenty-fourth annual meeting of which is being held to-night.

Mr. R. Dean seconded the adoption of the report, and the proposition was passed unanimously. Messrs. Cole, Berry, Dickens, and Kelf were elected on the Committee in the place of retiring members. A gift of £25, generously offered by Mr. Sherwood, towards the formation of a convalescent fund for sending members recovering from illness to the seaside, was thankfully accepted, and it was thought with occasional grants from the benevolent fund Mr. Sherwood's contribution might be of great service in the manner suggested. Sundry votes of thanks to the officers and Chairman brought the proceedings to a close.

MANNERS AND CUSTOMS—A CATALOGUE COMMENTARY.

(Continued from page 115.)

Pride of Reigate (G. Paul, 1885).—Of Victor Verdier race, being a sport from Comtesse d'Oxford, with the usual manners and customs of the family. This Rose has at least the merit of being the most distinct in colour of all H.P.'s, so that the merest tyro could pick it out anywhere, for it has the dark ground shade of the original from which it sported, striped and splashed with white. The result is not pleasing to me personally, but that may be a matter of taste. The old Damask Rose, "York and Lancaster," which had more white, and a fairly bright red instead of a somewhat dull carmine, seemed a more attractive combination of colour; but I do not think a striped Rose will ever find great favour.

Pride of Waltham (W. Paul, 1881).—Another of the same family, being also a sport from Comtesse d'Oxford, and a very valuable one. As a show Rose this is perhaps the best of this important race, for it is as good a grower as any of them, and the blooms are very large, opening well to a grand shape with stout petals. Even Waltham may well call this Rose its Pride.

Prince Arthur (B. R. Cant, 1875).—Of good though not stiff growth, and fair foliage; liable to mildew, but not much injured by rain. The blooms come generally well, and have very good lasting qualities, though the petals are rather thin. I gather from Mr. Cant that the origin of this Rose is rather obscure, but the general appearance points to Général Jacqueminot as an ancestor. It is, however, much darker in colour, and with me much larger and better in every way. A capital Rose, of pointed shape, very free blooming, and fairly good in autumn, but requires good soil and generous treatment.

Prinee Camille de Rohan (Verdier, 1861).—Syn: La Rosière. Of good growth and foliage, very liable to mildew, and to burn in a hot sun, but not much injured by rain; thin and apt to show an eye; very free blooming, and good in autumn; below the average size, but remarkable for its colour. Still the darkest of all Roses when grown strong, and velvety to the highest degree. Being much the oldest of all the dark Roses of merit, it was a very well known name in past years (better known in this country, I should say, if it is not treason, than the Prince himself), but has not only been passed in the race by larger and more enduring sorts, but has also apparently deteriorated in itself. Though hardy, a good doer, and easily propagated, it always requires to be grown strong to show its true colour, for it will come of quite a different hue—more of a scarlet crimson—on weakly shoots. Requires a thoroughly cool season, and came to light again wonderfully in the shows of 1888, being hard to beat at any time as a thoroughly dark bud for a buttonhole.

Queen of Queens (W. Paul, 1883).—Another of the Victor Verdier race, with the usual habit. Was quite good with me in 1887, but all my plants of it have gone off very much, and I have not had a good bloom since. This may, of course, be accident, but I do not think it can be reckoned among the best specimens of its tribe.

Reynolds Hole (Paul & Son, 1872).—A seedling from Duke of Edinburgh, of long strong growth when in health, with smooth characteristic

wood, but by no means of strong constitution, for the plants are sadly apt to become weak and die. It is liable to mildew and to injury from rain; a good average of the blooms come well shaped, but the weather must be hot and dry or neither colour nor form will be perfect. The flower is well filled in the centre, lasts extremely well, and hardly ever shows an eye; but it opens slowly, and must not be cut for exhibition before it is expanded, for neither long journeys and hot weather, pencils or budding knives, force or violence, will make it open except on the plant. It will not put up with light soils or the Manetti stock, is not very free flowering, and, being so dainty, cannot be expected to become a good autumnal. But a good bloom of it is truly superb, in petal, shape, colour and size, worthy of the name it bears of the President of the N.R.S., who has done so much to render Rose growing popular.

Sénateur Vaisse (Guillot, 1859).—Of fairly strong growth and constitution, and not very liable to injury from mildew or rain. The blooms come pretty well, with fair petals, good centre, fair size and good colour. An old Rose that still holds its own, a free bloomer and good autumnal; hardy, fragrant, and not over-particular as to soil, but must be grown strongly to show its brilliant colour at the best.

Souvenir de la Malmaison (Belusc, 1843).—This is not, strictly speaking, a Hybrid Perpetual, but a Bourbon Rose, and as I shall not name any other of that race, and it would have to be shown among H.P.'s by N.R.S. rules, it does not seem worth while to give it a section to itself. The growth and foliage are good and characteristic, not liable to mildew, but rots instead of opening in a wet season. The first crop of blooms come badly, many being divided and some quartered; at all times it opens very flat, a form admired by few and practically unrecognised now among show Roses. A very free bloomer and, as becomes a Bourbon, sweet scented and coming even better in the autumn than in the summer. This is a Rose of considerable reputation, which I regret that I do not admire; perhaps old associations enable it to maintain its position, for I do not think it would hold its own if introduced now as a novelty.

Star of Waltham (W. Paul, 1875).—Of strong growth in rich soil with magnificent foliage, not very liable to mildew, but will not stand rain. This Rose cannot be depended upon to come good, but is a splendid bloom when seen at its best, in petal, shape, colour, smoothness, size and lasting qualities. Not one of the best as a free bloomer or autumnal, and will not grow in poor or light land, requiring the best of weather and the richest and strongest of soil to show its good qualities to perfection.

Sultan of Zanzibar (Paul & Son, 1876).—Somewhat similar in wood to Reynolds Hole, of weak growth though often marked "vigorous." A Rose of very bad constitution with me, for I simply cannot keep it alive, and had never had even a decent bloom. It would probably have dropped out of the lists before now but for its magnificent colour—maroon, edged and shaded with very bright red. I have given it up, as it is no use wasting room on a variety which makes absolutely no return, even as a maiden.

Thomas Mills (Verdier, 1873).—Of very strong growth and good foliage, not much liable to mildew or to injury by rain. The blooms come well in fine weather, but are thin and most deficient in lasting qualities. The colour (scarlet crimson) is very bright, the shape pointed and imbricated (exquisite), and the size large; but it is a veritable snare for the inexperienced exhibitor, who finds it impossible to believe that those glorious half-opened flowers are really not worth taking. It might do in very cool weather, but the colour and shade are then deficient. Glorious at times in the garden in the early morning, and said to do well in northern counties. A fairly free bloomer, but not a good autumnal, many of the secondary shoots forming wood only.

Ulrich Brunner (Levet, 1881).—A seedling from Paul Neyron, of splendid stout stiff growth and foliage, untouched by mildew, and standing rain fairly. The blooms come very well, of extra large size, with stout petals tightly incurved in the centre, fine regular smooth shape, and capital lasting qualities, though the freshness of colour soon fades. A great Rose in many ways—free blooming, and capital in the autumn; hardy, and does well almost anywhere. When asked some time ago to recommend the two most useful varieties to a landlord who wished to give a good H.P. standard Rose to each of his cottagers, I selected La France and Ulrich Brunner as being the most likely to give satisfaction.

Victor Hugo (Schwartz, 1884).—Of fair growth and foliage, liable to mildew, but can stand some rain. This Rose is described in one well-known catalogue as "almost full," words which in catalogue English are generally absolutely damnable of a show Rose; but with me the blooms come well, fair in petal and centre, of good shape, glorious colour, and fair size. This is a very taking sort from its glowing colour, seems to have a good constitution, and on rich soil to be a good doer; fairly free in bloom in summer and autumn, but the flowers are not very lasting. The sort of Rose of which an exceptional bloom, like the one which gained the medal at Sheffield, will attract great attention.

Victor Verdier (Lacharme, 1859).—This Rose, as noted by Mr. G. Paul at the Rose Conference, has probably some slight admixture of Tea Rose blood (I suppose the phrase is legitimate; one must say "blood," not "sap," when treating of breeds and breeding); at all events the entire habit is most distinct, and it has become, as we have seen, the parent of a large and valuable race of smooth-wooded Roses, all of which show the family traits in almost every particular. For a description of manners and customs see Comtesse d'Oxford. The majority of those which have been noted are superior in many respects to this, their common ancestor.

Violette Bouyer (Lacharme, 1881).—A seedling from Jules Margottin, of free, vigorous, long growth, with good foliage very liable to mildew. This Rose comes very well, of a most useful shape, the outer petals falling well down before the centre uncloses; it thus makes the most of itself, and never requires any dressing. It cannot stand any rain, like Madame Lacharme, and, like it, is liable to show injury from thrips, the petals being delicate in texture. The outer petals only are tinted with pink, and often the whole Rose is pure white. It is very free blooming, and good in a dry autumn, also hardy and strong in constitution, but loses in value from its dependence upon fine weather.

Xavier Olibo (Lacharme, 1864).—Evidently a seedling from Général Jacqueminot, as the wood is very similar. A weak grower with bad constitution, rather liable to mildew, and not enduring rain well, which answers best if budded annually, but occasionally does fairly well as a cut-back. The colour of this Rose is generally catalogued as "velvety black, shaded with amaranth," which is a very taking description, especially to those (if there are any beside myself) who have but a hazy idea of what amaranth is as a colour. I thought it was a flower, not a colour, and the sort of flower more often found in books of poetry than in actual gardens. Moreover, I confess that having seen first-class specimens of Xavier Olibo, which sometimes produces a very fine dark bloom, I am still uncertain as to where the amaranth "comes in," as the Americans say. Dark crimson, shaded darker, and velvety in favourable specimens, would be my description, but I dare say it would not be right. I know that it is difficult to describe the various shades accurately. The blooms come divided sometimes, the petals are stout and the centre full and recurved, but sometimes nicely pointed; a good luster, of full size. It will not answer on poor soil, and from its weak growth is necessarily not good as a free bloomer or autumnal.—W. R. RAILLEM.

(To be continued.)

EUCCHARIS GRANDIFLORA.

IN your issue of January 30th I notice an article by Mr. W. Taylor, entitled "Destroying the Eucharis Mite." Like Mr. Taylor, I do not believe the Eucharis is altogether a hard plant to cultivate, but I cannot understand their doing fairly well either baked, stewed, or poisoned. I contend the best way to renovate bulbs that are in ill health (which I prefer to call it rather than attacked by mite, as I think the one follows the other as a matter of course), is to cut away the roots and leaves and wash the bulbs and place in small pots, say three bulbs in a 6-inch pot, like Mr. Taylor, and remove when filled with roots.

I prefer washing the bulbs in warm water, as I find it safer to kill the mite by good treatment rather than have recourse to so-called mite killers, which I think I am safe in saying have sent more bulbs to the rubbish heap than any other cause. The wash Mr. Taylor recommends I consider no more effectual than water, as one of my friends soaked his bulbs in a mixture of petroleum, &c., for twenty-four hours, the same being much stronger than Mr. Taylor used, at the end of which time the mite was still alive, but the bulbs hopelessly destroyed. When my own bulbs were first attacked through coming in contact with some fresh bulbs I bought, I, like many others, tried to cure a portion of them by dipping them in a strong solution of petroleum and soft soap, which killed instead of curing, and those I left alone to be cured by cultivation succeeded beyond my expectations. Another Eucharis grower in our neighbourhood says my version of the matter entirely coincides with his experience, he having killed bulbs he tried to cure by dipping, and cured those he left alone. Doubts exist in some people's minds as to my bulbs having been attacked by mite, but that they were attacked by mite and also by a fungus is a fact, to which Mr. W. B. Grove of the Mason Science College, Birmingham, can testify. I observe that one vendor of a mite killer in advertising same in your columns, says that bulbs which four months ago were leafless and eaten by mite all over and into the scales are now in healthy leaf and throwing their flower spikes. If this be so, I think this wonderful recovery in so short a time should go a long way to prove that the ravages caused by mite are more imaginary than real, assuming of course that proper treatment is given.

The plants Mr. Taylor alludes to were bought at auction, and which quickly responded to a liberal treatment, but after being divided and repotted soon fell into a sickly condition, making new leaves only to lose them prematurely. These, I presume, were repotted with roots and leaves left untouched; in which case, unless the bulbs are exceedingly healthy, the roots have a tendency to decay and encourage insect life, and the leaves a tendency to push unsupported by anything except what remains in the bulb, which it soon exhausts, and the atmospheric moisture of the house. After a short time this support proves to be altogether insufficient, hence the leaves getting into the flabby condition alluded to by Mr. Taylor; whereas if roots and leaves had been removed in first instance, which according to Mr. Taylor's letter had to be done before any good result was obtained, I think he would have been able to say the bulbs responded to the call without the aid of petroleum and Fir-tree oil. I find that by the removal of leaves the bulb becomes, as it were, sealed for a time, and the slimy substance so necessary for the after development of roots and leaves preserved, without which I think it is useless to attempt to grow the Eucharis successfully, as the drier the bulb becomes the less the chance of success, and the easier it falls a prey to enemies.—HENRY PORTER.

FRUIT FORCING.

VINES.—Early Forced House.—The Vines in flower must have a temperature of 60° to 65° at night, and 70° to 75° by day artificially. Keep the atmosphere somewhat drier by free ventilation, leaving a little air on at night, yet keeping the floors sprinkled three times a day during bright weather. Any shy-setting Grapes may have the pollen distributed by brushing the bunches lightly with a camel-hair brush. Stop the laterals at the first leaf, and keep them stopped to one leaf throughout the season, but those beyond the bunch may be allowed to make two or more joints, provided there is space for the full exposure of the foliage to light and air. Avoid overcrowding the foliage; it is better to reduce the laterals than allow them to obstruct the light that would otherwise reach the principal foliage.

Houses Started at the New Year.—The Vines are in leaf and showing fruit. Disbud when it is seen which shoots are likely to afford the best bunches. One bunch on a spur is as much as is likely to finish satisfactorily; but if there be space, the spurs being widely distant along the rod, two shoots may be left, it being clearly understood that only one is to be allowed to carry fruit, the duplicate only remaining until choice can be made of the best, and in case of two shoots being left, one ought to be near the main rod, so as to keep the spur as short as possible. Weakly Vines, however, may be given more latitude, so as to secure stouter wood, larger and plumper eyes, and better bunches in future. See that outside borders are sufficiently protected to prevent chill by heavy rain or snow. When the Vines are in leaf the temperature should be raised to 60° or 65° at night, 5° less in severe weather, 70° to 75° by day with sun, admitting air carefully in sharp weather, but freely whenever the external conditions are favourable, in order to the formation of stout firm-textured foliage.

Houses to Afford Grapes in July and August.—The Vines must now be started. Damp the rods three times a day, and every available surface. A temperature of 50° at night, 55° by day artificially, and 65° from sun heat, is suitable until the buds begin to move. Bring the inside border into a thoroughly moist state by repeated supplies of tepid water or liquid manure. Afford outside borders sufficient protection against chill. Any young rods or canes should be depressed to the horizontal line, or lower, to insure the buds breaking regularly.

Ripe Grapes.—Avoid fire heat as much as possible in the Grape-room, admitting air to prevent an accumulation of moisture, replenishing the latter with clear soft water as required. An equable temperature of 45° is most suitable.

New Borders.—Soil should now be prepared, and the best for the purpose is the top 3 or 4 inches of a rich pasture of a friable nature, neither very light nor very heavy. As that is not always obtainable light loam may have an addition of clay marl, and heavy loam an addition of old mortar rubbish, a fourth to a sixth in each case according to the texture of the loam. To improve the porosity of the compost a sixth of old mortar rubbish may be added to the loam, being careful to remove every particle of wood. A twentieth part of charcoal may be added, and a fortieth of crushed bones. Calcined oyster shells may be used in similar proportion to the crushed bones, also wood ashes. Chalk is a good application to light silicious soil, employing it to the extent of a fifth. If the soil be poor a fifth part of short fresh stable manure or horse droppings may be added. It is best, however, not to apply material which when spent forms a close mass. The whole should be well incorporated.

In preparing the border, which may be proceeded with as weather permits, bear in mind that no fruit tree requires more copious supplies of water when in growth than the Vine, and at the same time none is more impatient of stagnant water; hence drainage should receive first attention, and instead of excavating, concreting, and cementing keep the border well elevated as far as circumstances permit. Employ 3-inch drains with proper fall and outlet. Provide a foot in depth, material, the roughest at the bottom and the smallest at the top, which last preferably may be old mortar rubbish. If the border is intended for early or late Vines allow a sharp slope to the south for the purpose of throwing off the wet by shutters or other means. The best time for planting Vines is from April to June inclusive, and those intended to be planted at that season must now be cut back to the length required, and be placed in a cool Peach house or pit to start into growth, and when the new shoots are 2 or 3 inches long shake out the plants and plant them in the permanent borders. A 6-feet width of border will be sufficient in the first instance. Where the Vine roots are to have the run of both inside and outside borders they should be confined inside, not making the outside border until the Vines are thoroughly established.

CHERRY HOUSES.—These are not nearly so common as they deserve to be, indeed no fruit is so esteemed at dessert as the Cherry. A lean-to house erected against a south wall is suitable for Cherries, and it need not be more than 6 feet in width. The back can be covered with trees, and the front to a height of about 6 feet, with trees on the Mahaleb stock. Provide ventilation at the top and bottom of the house, and the front lights to be moveable. The border should be made inside, though

the roots may have access to an outside one. Thorough drainage must be provided, so as to carry off superfluous water. Rather strong loam is most suitable, adding about a sixth of old mortar rubbish and a fifth of road sweepings. Trees from the open wall between four and six years trained, if carefully removed to the house, come into bearing at once. Water them well to settle the soil about the roots, and ventilate freely, syringing in the morning and early afternoon, employing fire heat only to exclude frost, but when the trees are fairly in growth let the day temperature from fire heat be 50° to 55°, rising to 60° to 65° from sun, increasing the ventilation at 55°, and close at that temperature, leaving, however, a little ventilation on day and night, 40° to 45° at night from fire heat will be sufficient. May Duke, Black Tartarian, Elton, and Governor Wood are suitable varieties for forcing.

KITCHEN GARDEN.

FORCING.—Vegetable forcing may now be practised with success and little trouble. Rhubarb and Seakale grow readily with the aid of a fermenting bed placed over the crowns and pots, and Asparagus is ready in ten or twelve days after being placed in a temperature of 65° or 70°. Surplus roots of all these should be used for forcing before the season is further advanced, but there is no economy in forcing roots that are required to keep up the desired supply when the time comes for them to grow naturally. Those who force roots should always provide some for the purpose without having to interfere with the ordinary stock.

KIDNEY BEANS.—December reared plants are now in flower, and require to be kept well supplied with water at the roots, but in a somewhat dry atmosphere, as the flowers will decay if kept very humid. The pods will swell rapidly in a temperature of 70° or a little less, and they are all the better for being kept well up to the light. We do not, however, approve of keeping them in vineries or Peach houses, as they are somewhat apt to be infested with red spider, and if it gains a footing on the Vines or trees thus early it may prove injurious before the season is over. Sow a large quantity of seed, as this will produce plants at a time of the year when they will bear heavily. We regard Kidney Beans as one of our most useful forced crops in April and May.

PEAS AND BROAD BEANS.—See that birds or slugs and snails do not injure the young plants now coming through the soil. Sprinkle them with lime or soot, put a little ridge of finely sifted ashes along each side of the rows, and give protection by placing a few short twigs in as stakes. We save all our old birch brooms during the summer to use in this way. Sow more seed of both Peas and Beans, still giving them the best position in the garden, and only using the earliest varieties.

GROUND FOR CARROTS AND PARSNIPS.—Few soils are naturally suitable for these two important crops. Both require deep ground, and neither succeeds in a heavy wet soil. Grubs and worms are especially enemies to Carrots, and fine clean roots will only be produced in a friable soil that has been cleared of all pests. Of late we have been carting refuse recently cleared from a pond, which consists chiefly of decayed leaves and sand, on to our Carrot and Parsnip quarter. It was laid on about 1 foot deep; some old Mushroom bed material, a quantity of soot, and a little lime were added, and the whole trenched and worked in to a depth of 18 inches, and the best results may be anticipated for several years to come. All growers may not, however, be able to secure pond refuse, but road scrapings may be substituted, and soot or lime should not be forgotten. Ashes too, especially when partially obtained from wood, are useful on heavy soils, and the preparation of a piece for Carrots and Parsnips on lines somewhat after those suggested will amply repay cultivators.

SPINACH.—The autumn-sown prickly sort has been luxuriant all the winter, but it becomes coarse in spring, and as Spinach is one of the first crops that may safely be sown in the open several rows may be put in on the first opportunity. The plants early in the season run rapidly to seed, and that is the reason why we always sow in small quantities and often. A sunny sheltered corner is the best position for it thus early.

CABBAGES.—As these have received little or no check the whole winter they promise to be ready unusually early in the spring. Make up the blanks in the rows, clear the dead leaves and weeds from amongst the plants, and draw a little more soil to the stems with a drag hoe. Should there be a deficiency of plants in the main quarter manure and dig another piece of ground, and plant out more from the seed bed. We have often found this plantation in almost as soon as the autumn planted ones, and our practice is always to plant out some in the spring, no matter how extensive our autumn lot may be.

TOMATOES.—Cuttings rooted in the autumn should be potted into 6-inch pots. Do not give them a rich soil, as this only induces them to make superfluous growth. Make the soil, which should be chiefly loam, very firm round the roots, and place them near the glass in a temperature of 65° or 70°. These plants will fruit before any of this year's seedlings. Those who omitted to take cuttings, however, must depend on seedlings. Do not give them over-rich soil. This is a rule we apply to all Tomatoes, and keep them growing in brisk heat. Plants that will fruit in March and ripen in April must be confined to one stem and placed in favourable positions in the houses. Where they are grown as a market crop plant them out in the forcing pit like Cucumbers, 1 foot apart, but do not give more than an 8-inch potful of soil to each plant at present, as this is ample to make them produce fruit, and more can be added if necessary.

Sow a little Lettuce seed again in a pot or box under glass, also a pinch of early Celery, Leek, Cauliflower, and Brussels Sprout seed; but avoid as yet sowing anything like the main crop of any of them.

PLANT HOUSES.

French Pelargoniums.—Some of the earliest plants will be showing their flower trusses. These must not be unduly hurried, for no advantage is gained. If they are kept too warm and too close the foliage soon draws up weakly, and the appearance of the plants is destroyed. This is not all. The plants fail to flower so long and satisfactorily as if they had been brought forward a little steadier. What they need is a position close to the glass, where the temperature ranges 50° to 55°, with a free circulation of air amongst them whenever the weather is favourable. Later plants should be kept cool to induce strong sturdy growth. A number of plants that were rooted early and placed in December in their flowering pots will be filling them with roots. A little artificial manure applied to the surface of the soil will benefit these. Soot water in a clear state acts quickly, and imparts to the foliage a dark healthy appearance.

Plants that were pinched some time ago should have broken strongly, and may without delay be placed in their flowering pots. Old plants that were grown strongly last year and cut hard back rather late in the season will still be weak. Pinch the shoots as soon as they are long enough, and in a cool house they will break strongly and gain strength rapidly. As soon as they fill the small pots in which they were placed they should be transferred to those in which they are intended to flower. Plants that were struck late are still in small pots and ready for pinching. As soon as they break again transfer them to a size larger. Do not push them on in a close confined atmosphere, for they only grow weakly, and time in the end is lost. Cuttings of young wood will now root freely if inserted singly and placed in a temperature of 65°. In potting these plants press the soil firmly into the pots, and use for a compost fibry loam, one-seventh of manure, and sand. To this may with advantage be added a sprinkling of soot and artificial manure.

Fuchsias.—Cuttings are now plentiful, and will root freely in boxes that can be covered with a square of glass if the boxes can be placed in vineries or other houses where the temperature ranges 60°. As soon as they are rooted place them singly in small pots, and grow on a shelf close to the glass to prevent their drawing. Sturdy growth from the first is necessary to have handsome plants well flowered in small pots. Autumn-rooted plants should be placed into 5-inch pots. For these use a compost of loam three parts, the other part being composed of leaf mould, sand and manure, or old Mushroom bed refuse.

Lantanas.—Plants at rest may be pruned back and started into growth in a vinery or Peach house. Good syringings daily will be ample until the plants show signs of breaking, when they should be turned out of their pots, the roots reduced, and the plants repotted in a smaller size. It will then be necessary to water them carefully until they display signs of active growth. Young plants rooted in August or September and kept gently moving through the winter should be placed into 5-inch pots. If placed in an intermediate temperature and the shoots pinched from time to time they will soon make bushy little plants.

Callas.—Plants that have been flowering for some time should be supplied with weak stimulants every time they need water. If they are to continue flowering they should be encouraged to grow, or they soon come to a standstill. Plants that have been kept perfectly cool will soon come into flower if they are placed into an intermediate temperature. Where it is necessary to increase the stock suckers may be carefully removed and potted singly. Small pieces will make strong flowering plants another season. Aphides are the greatest enemies these plants have to contend against; slight fumigations of tobacco smoke will destroy them, but if done strongly the spathes are liable to injury. They can be kept down by a free use of the syringe. If the spathe is damaged in appearance by them it can be cleaned by the aid of a soft sponge under a tap of water. The supply of water for this purpose must be abundant, or else the spathe is damaged.

THE BEE-KEEPER.

HINTS TO BEGINNERS.

EARLY POLLEN GATHERING. — FEEDING.

THE month of January was mild but stormy. The temperature on the 16th was 52° Fahrenheit, and the bees for the second time were busy on the Arabis, and gathered pollen from it on the 12th of the same month.

As some of my nuclei had only 8 lbs. of sugar since they were formed, and built from that 4 square feet of combs, it fully refutes the 20 lbs. of honey for the pound of wax theory. Taking advantage of the extra mildness I fed those with from 4 lbs. to 6 lbs. of sugar. I was apprehensive of being short of stores. Singularly, the fed bees have flown the least. There are few dead bees about, and only one shows signs of abdominal distension, and that is the only one that I withheld syrup from in the autumn.

To prevent every form of dysentery I feed every stock in autumn with a few pounds of the best sugar syrup, covering closely on top and sides with soft well-dried meadow hay, narrow entrances with space below ventilating floor, which gives an entire immunity from damp, unless upon the very top of hay on top of hive, which is the index to a dry hive and healthy bees within. The syrup will tide them over in safety until April, when an examination may take place, but as little as possible. I always make sure that March will not find hungry bees, it being the worst month in the whole year to have hungry bees or weak hives. But the considerate bee-keeper will seldom have to manipulate one way or another with bees during the winter and spring months, unless with chance nuclei not intended to be kept over winter during September. As the foregoing hints plainly show what to do in the case of an emergency, and what to avoid in winter and spring, I will now say something on another subject.

WINTER PREPARATION.

I have shown that bees can be kept healthy during winter ; but this may be done, and yet with all care many hives may be lost on the sudden rise of temperature during January, February, and March, which takes place on the breaking up of a snowstorm or immediately after a snowfall when the day is lengthening. On these occasions the bees rush out of their hives in great numbers, either to be lost among the newly fallen snow or chilled to death in the melted water, rendered all the colder by the partially melted ice lying everywhere about where the snow has been trod, or in all hollows. To prevent any mishaps at these times the bee-keeper should be on the watch, and whenever signs of a rise in temperature is indicated by thermometer and barometer the doorways of the hives should be effectually closed, and ventilation afforded by some other part. On no account close the entrances of hives with wire-cloth or perforated zinc, as being sufficient for the purpose, for the bees will crowd to it, and then suffocation soon follows. The hive that cannot be properly ventilated on these occasions is a very imperfect one.

The beginner will now have a fair idea what a hive to winter bees in should possess. Long before the winter sets in site and appearance of the hive, as well as the arrangement of it, should be completed. Only the other day a loose cover of cloth was blown from a heap of odds and ends lying near the ground and blown between two hives, which marred the bees, and many were lost although the front was perfectly open. Perhaps during this time, when so much influenza is about, it may not be out of place to state that many such colds are contracted by the patient having previously heated himself by putting on more clothing than was necessary, just as I have often witnessed thinly clad children keeping free from colds until new shoes or other garments had been added. Something similar to this arises with bees when their doorway is contracted or widened during changes of weather in winter. A uniform degree of heat at all times is what should be studied with our persons, as we should do with hives of bees.

When bees are placed into a hive the first thing they do is to make the top of the hive air-tight, but in a great measure disregarding the sides, and wholly the bottom. Their instinct teaches them that any draught whatever above them has the evil influence of cooling the interior of the hive, sending moisture into the honey, and making the bees restive and unhealthy.

Although these facts might be apparent to a mere child, yet leaders in bee-keeping matters advocate in favour of the American plan of making a cavity overhead the bees either by bent sticks or a ceil of candy, a more unsuitable food for bees than honey, although excellent as a substitute when neither honey nor syrup can be conveniently given. The advocates of this space overhead tell us that it is the warm place of the hive where the bees are fond of creeping into. Common sense would say that the bees finding a draught overhead endeavour to fill up the vacuum, and by so doing they retreat above their natural stores, leaving them

unprotected from both animal enemies and the humid atmosphere, which renders honey unwholesome and the pollen of the hive a capital nidus for the germs of foul brood. Where is the heat to come from to heat the upper cavity with cold ceil of candy, but from the some bees that would, had Nature not been perverted, remained in their hive in a healthy state as Nature had dictated, keeping their stores wholesome and protected from damp and other enemies ?

The beginner should use his judgment in detecting between right and wrong, and his wisdom in rejecting the latter. Some writers have led themselves and others astray by comparing bees to other animals' wants of breathing space, overlooking the fact that there is a wide difference between the insect and the biped or quadruped in their breathing functions. From 50,000 to 100,000 bees will cluster into a space, and be so crowded that more would have to lie out. Yet with only a very small doorway the whole cluster will remain healthy. Pack as many men in a proportionable space, with a proportionable doorway, an epidemic of some sort would soon be upon them.

It is altogether impracticable to make comparisons between bees and man. Bees require air, but a very small stream of it suffices from the fact that, unlike man or other animals, they carry a supply with them in addition to their immediate wants, and it is through this supply being heated in the system that enables bees to survive our arctic winters when allowed to repose quietly in that state termed hybernating by "A. H. B. K." This natural heated air given out by one bee and inhaled by another, has never been mentioned before, and the cause of dysentery amongst bees is when the arrangement of the hive is defective, or when bees are disturbed so as to exhaust the heated air, and are unable to take in and heat a new supply, disease follows.—A. L. B. K.

TRADE CATALOGUES RECEIVED.

Benjamin Wallace Knight, North Trade Nursery, Battle, Sussex.—*Catalogue of New and Choice Plants.*

T. T. Green, Duke Street, Settle, Yorkshire.—*Descriptive Spring Catalogue, 1890.*

Friedrich Adolph Haage, Jun., Erfurt.—*Illustrated Catalogue of Plants and Seeds.*

Webb & Sons, Wordsley, Stourbridge.—*Annual Catalogue of Farm Seeds.*

James Yates, Stockport.—*Catalogue of Vegetable and Flower Seeds.*
Strachan & Thomson, 145, Union Street, Aberdeen.—*Catalogue of Vegetable and Flower Seeds.*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Drainage (F. M.).—We do not understand what you mean, for you first write malting very plainly, and then just as plainly matting. If you can state the nature of the drainage we will endeavour to ascertain its probable constituents.

Sizes of Pots (W. A. B.).—Please quote the page of the essay you mention in which the reference appears. Pot manufacturers sell by "casts," and a No. 4 cast, or 4's, are 15 inches wide across the top, and 13 inches deep; a No. 2 cast, or 2's, 18 inches wide across the top and 14 inches deep.

Trade Dealings (J. S.).—It is impossible we can form an opinion on the case in the absence of the "chapter and verse" referred to, but in our experience more than half the "showing up" articles we receive affecting individuals are libellous, notwithstanding all that may be true in them, and we act accordingly.

Protecting Apricots (C. H.).—Under the circumstances you describe nothing could be better than glass protectors, either moveable or abundantly ventilated, so that the period of blossoming is not advanced. The earlier the expansion of the flowers the greater their liability to be injured by sharp spring frosts, even under glass, where no artificial heat is afforded and no other covering applied.

Tomatoes (H. G.).—It is seldom that Wednesday morning letters can be answered in the current issue, and we can only say briefly in answer to yours that the house may be closed early with sun heat, but not so early as a Cucumber frame, nor with half so much moisture. Still the atmosphere must be pleasant and genial. Syringing is only occasionally needed. Firm growth is the desideratum, and this is the result of firm soil, full light, and judicious ventilation.

Protecting Strawberries (F. J.).—Many persons have found it profitable to cover strong healthy Strawberries with sashes for accelerating the ripening of the fruit by a week or ten days, but the extent of profit derivable from the plan depends entirely on the character of the plants. A 13-inch board firmly affixed on edge for the back of the enclosure, and a 9-inch board along the front for the sashes to rest on, will suffice for your making the experiment. We are unable to decipher the name of the plant on which you ask for information, and suspect it is something misspelt. Please describe the plant, and we may perhaps know what is meant. We may add, however, that the time of flowering is not suitable for transplanting.

Treatment of Pancratiums (S. S.).—Those that have had a good season of rest may now be repotted or top-dressed. If the latter, use two-thirds loam and one of cow manure prepared as previously advised. If they need the former the compost advised for Eucharises will suit these plants well. Too much drainage should not be employed, as the plants root deep and with great freedom. In repotting shake away the whole of the old soil from the roots, and be careful not to bury the bulbs, or a large per-centage of the soil will not contain a single root. Spread out the roots carefully near the surface, for they are certain before the end of the season to be crowded round the drainage. These plants will grow in almost any position in the stove after potting until they are again established, even standing under the shade of large plants; syringe liberally, but do not give too much water. Watch for thrips, for if there is any in the house they are certain to attack the under side of the foliage of these plants.

Apple Royal Somerset (G. D.).—Yes; the variety is in cultivation, and Messrs. Laing & Sons of Forest Hill recently sent an excellent specimen. It is thus described in the "Fruit Manual":—"Fruit rather above medium size, 3 inches wide, and rather more than 2½ inches high; roundish ovate, generally higher on one side than the other, handsome and regularly shaped. Skin smooth, pale yellow, with a tinge of green on the shaded side, but brighter yellow, marked with faint broken streaks and mottles of crimson, on the side next the sun; the whole strewed with russety dots, which are most numerous in the basin of the eye. Eye large and open, with very short, stunted, erect, divergent segments, placed in a round, even, and pretty deep basin. Stamens marginal or median; tube conical or funnel-shaped. Stalk upwards of half an inch long, slender, and inserted almost the whole of its length in a deep, round, smooth, funnel-shaped cavity. Flesh yellowish, very tender and juicy, with a pleasant, delicate, sub-acid, but not brisk flavour. Cells ovate, axile. A very excellent culinary Apple; in use from November till March. Like the Dumelow's Seedling this Apple is translucent round the eye. The Royal Somerset of the Horticultural Society's Catalogue is London Pippin; but the variety described above is a very distinct fruit, and has more the resemblance of a medium-sized Blenheim Pippin, both in shape, colour, and the formation of the eye. I obtained this in 1847 from the late Mr. James Lake, nurseryman of Bridgewater.

Endive and Spinach (F. N.).—We do not think you will find Endive so profitable a crop as Lettuce; in fact the demand is not nearly so large. If you are close to a market where there is a good demand for Endive it might pay you as a catch crop, being better than having the ground vacant. We have seen it stated that 1s. a dozen can be obtained for Endive, and we do not doubt this. If that price for a good crop can be realised it will pay well. But we have grave doubts whether large quantities could be disposed of to pay for the trouble and labour of planting. It is easily raised and not long on the ground, and if there were a ready sale it would prove most remunerative. We know a market grower in the neighbourhood of a large provincial town who grew Moss-curbed and Round-leaved Batavian, but could not dispose of sufficient to pay him for the labour of planting and the seed. If you decide to try, we advise you to plant a small quantity at

first until you find out whether you can dispose of it at profitable returns. The seed should be sown thinly in beds from the 20th of June to the middle of July. The plants should be placed out during showery weather, when large enough, 1 foot apart. In some markets there is a good demand for Spinach more or less throughout the season. We have found it sell very well early in the season, and for this purpose it is a good plan, where it stands well through the winter, to sow on slightly raised ridges, and thin out the plants liberally. If allowed to crowd one another they seldom do any good. This is sown during August, from the middle to the end of the month, on ground that is to be occupied with early Peas. A sowing should be made during the few last days of March, and successional sowings should be made at intervals of a fortnight, in any space where it can be cleared off without damaging the main crop, of whatever it may be, against which it may be growing. We have seen useful and profitable rows grown on the narrow strips of ground that divide one crop from another. For instance, the space between the last row of Onions and the first row of late Potatoes, if they follow close to the Onions, and so on. Ground that is ready early in the season and intended to be planted with late Potatoes 2 feet 6 inches apart, can have a thin row of Spinach sown between them. It must be cleared off directly it is ready, so that the ground can be worked between the Potatoes. We advise you to treat Spinach as a catch crop only, and grow it between early crops, and after they have been cleared from the ground. We have known Spinach pay well early in the season, after a severe winter, for sowing on a warm border and covering with an old frame or two, and a few spare lights. We advise you to try small quantities first, and when you have decided upon your market you will be able to judge from the returns of the salesman you select whether it will pay you to grow, and you would also be able to ascertain from him about what quantities he could dispose of for you.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes, slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. —(E. H. B.).—Doryopteris palmata. (G. T.).—1, Adiantum decorum; 2, Asplenium bulbiferum; 3, Todea superba.

COVENT GARDEN MARKET.—FEBRUARY 12TH.

Our Home Market is completely stagnant, supply being entirely dependant upon imported goods. Good samples of Grapes are now coming short, and realising good values.

SEED TIME.

AGAIN has the time come round for the selection of enough seed for sowing requirements during the coming spring and summer, and it is of especial importance that the selection should be made with judgment, and due care taken both as to sorts and per-centage of germination, in order to reduce liability to loss or failure as much as possible. An outlay approaching the borders of extravagance upon seeds is advisable upon the principle that none but the best should be sown, best in the full meaning of the term—i.e., in purity, soundness, productiveness, and general high quality. It will not, however, answer to procure seed corn in large quantities from seed merchants, and we have found that an intimation of our requirements to local factors at market soon renders superior samples forthcoming at rates only a little above ordinary market quotations. So important do we consider it to sow pure samples of the very best description, that all seed corn, whether purchased or home grown, is screened repeatedly till we are satisfied that all tail corn and weed seed is got rid of. It requires a modern screen in perfect order to do this work well, and this is one of the reasons why we never purchase an old or much worn winnowing machine.

Of Barley there is no better sort than Webb's Chevalier, both for quality and quantity. The grain is large and heavy, and the ears very full and long, but we have never had such ears of it or any other Barley as the marvellous examples of novel sorts shown by the illustrated advertisements of certain specialists recently, and we have had upwards of 300 acres under this crop for several years. We have had ears of Chevalier with twenty grains on each side; that was our highest flight in Barley culture, they were magnificent ears, and the yield per acre was remarkable for its abundance. There is no doubt that mixed soil is the best of all for Barley; and though we have heard legends of wonderful crops of fifteen coombs an acre on heavy land, experience has shown it to be a most uncertain crop on such land, and also that it answers to give preference to such crops as Wheat, Oats, Beans, and Peas for it. If Barley must be grown for special reasons on heavy land, then it will be found that the beardless variety answers best.

Of Oats, Black Tartarian and Canadian White are equally good for spring sowing, but good samples of the Black Oat are scarce. One may go round to the stands of an entire market and not find a genuine sample of really first-class "Black Tartars." They are to be had, however, and we claim for them the best land and the highest culture, such as they receive in Scotland, at Lothian farms for example. When Wheat was the leading corn crop, it was customary in East Anglia to grow just a field of Oats, and the custom still finds observance on many a farm. But we have proved repeatedly that Oats repay one now for high cultivation if only the seed sample and land are both right. For heavy land especially we have no more profitable crop, few so good, and it certainly ought to replace Barley entirely on such land.

Clover sowing specially for seed will still be done, but we cannot hope ever again to find it as profitable as it used to be. The quantity left for seed last year was very large, much was spoilt, and much got so badly that fresh seed must be ordered with caution. The price is kept down by heavy importations of foreign seed, which is said to be excellent; but such seed so frequently contains Dodder that it requires almost microscopic inspection before purchase. For forage mixed layers are more and more taking the place of Clover pure and simple, and here the farmer can very well place his orders in all confidence with the specialist seedsmen. Nutriment in a more concentrated form is said to be found in the latest new sorts of Mangolds. The difference is merely one of degrees, and while we are able to obtain such heavy crops of Orange Globe and Long Red as we did last year, we shall have nothing to say to more expensive novelties. The seed should be ordered now, so also should the Swedes and other Turnips, and then the Mangold sowing can be done early in April, and the first sowing of Swedes, as the land is ploughed after the sheep folds on the Rye. Never heed the outcry of croakers about early Mangolds bolting to seed or Swedes becoming mildewed, but sow early, single early, and keep the hoes going early and late—horse hoes as long as they can be used without injury to the plant, and hand hoes while there is a weed to be seen.

WORK ON THE HOME FARM.

Never was the value of efficient under drainage more apparent than now, and the superiority of bush drains to pipe drains for clay land is well shown. Clay is so liable to seal the joints of a pipe drain and to render it practically useless, that although bush drains have to be renewed in about eight years they have preference with us for very heavy land, and we have been turning some overgrown hedges to account for that purpose both for new drains and for opening some stoppages in old ones. A few pipes only are used for the "eyes" or outfall of each drain, which is usually alongside of a deep ditch. The chief faults in the drains were seen and marked on the farm plans last summer, a "wet" place in a corn field caused by a faulty drain always being visible by the yellow and stunted growth. We may here note the importance of having a large working plan of every farm drawn to scale with the position of each drain clearly defined in it, so that it can always be found, and any fault marked and corrected in due course. The date of the making of each drain should also be entered, and also the material used. This is really a matter for the estate agent, but it also concerns the tenant so much that he should always have a duplicate of the plan, even if he is put to some expense to obtain it.

The action of drains depends very much upon the mechanical condition of the soil, and it has been interesting and highly satisfactory to see how the passage of rain water through the soil to the drains has been accelerated by heavy dressings of burnt clay, which have been worked in by plough and cultivator. This clay burning is done as opportunity offers during summer, and by it the quality and condition of the soil becomes much improved. We have been doing it gradually for some time, so that the expense has never been a heavy item in any year, while the progress made has been steadily going on year by year, and the value of the land has gradually increased. It is clearly the most economical and efficient way of soil division on a clay farm; it might even be said to be the only way on an outlying farm distant from any source of other hard materials.

REMARKS.

2nd.—Fine, with some sunshine in afternoon; clear moonlight night.
3rd.—Fog till about 9 A.M., then sunshine throughout.
4th.—Slight fog early, bright fresh day.
5th.—Dull damp morning; a little sunshine in late afternoon; bright night.
6th.—Cloudy, with slight snow and rain till 11 A.M., then sunshine and slight showers alternately.
7th.—Cloudy but fine.
8th.—Unbroken sunshine.
A very fine and seasonable week. On the afternoon of the 4th, when it was warm and fine sunshine here, it was so foggy in town that the cab had the lamps alight.—G. J. SIMONS.

APPLES AND OSIERS.

ON page 62 of the issue of the *Journal of Horticulture* of the 22nd ult., a Blantyre correspondent refers to packages for fruit, and observes that "Willows might occupy many acres of what is at present uncropped ground, and the making of hampers would give employment to many unable to perform other work." It is not on the question of hamper or basket making that I am about to enlarge, but will merely say that closely and strongly made round hampers are very suitable for and largely employed in the transit of fruit of various kinds for the London markets. They are known in the trade as sieves. A bushel sieve, similar to the one illustrated on page 115 of the essay I wrote for the Fruiterers' Company, is 17 $\frac{3}{4}$ inches in diameter at the top, 17 inches at the bottom, 11 $\frac{1}{4}$ inches deep, and holds ten and a half imperial gallons. The sieves or hampers are lined with paper, usually of a bluish tint, for contrast with the fruit, the ends of the paper being long enough for turning down and covering it. With a little fern or hay on the top, if not without, these packages can be stacked on the strong rims of each other without the contents being injured. They are similarly packed for returning empty, and when conveyed by road are piled up as straight as loads of hay are in the country, but a good deal higher, and made secure with ropes. Many salesmen supply these sieves to growers for sending their fruit to market, and the most uniform and best samples invariably meet with a ready sale. But woe to the man who "works in" trash below a covering of "toppers," for his character as a "dodger" flies like bad news, and his wares are shunned accordingly.

"W. T.," the correspondent alluded to, who is apt in contributing suggestive hints, says Willows might occupy many acres of uncropped ground, by which he possibly means ground that is not well adapted for growing food produce. The proposition is quite true, and much swampy or naturally wet land is so occupied, paying the owners or tenants much better than leaving it in a wild or uncropped state. But my object is to show that on certain soils the best of Apples and the best of Osiers can be grown together without either acting in the least injuriously on the other; indeed, it is not beyond the bounds of probability that the Osiers benefit the Apples rather than otherwise.

The combined Apple and Osier culture that I have had the pleasure of inspecting is conducted well and profitably a mile or two from Southwell in Nottinghamshire. The soil is strong, approaching clay, and for a number of years was of slight value to the owner. Several acres were purchased at a low price about fifteen years ago, and placed under the dual occupation of what, on paper, must appear a little incongruous—Apples and Osiers. Strong retentive soil is generally condemned for Apple culture, while Osiers and quagmires appear a natural association; but in the extensive plantation in question it would be difficult for the most experienced observer to determine whether the growth of the Apple trees or the Osiers is the more satisfactory. The best evidence that both have answered is found in the fact that the fee simple value of the land has much more than quadrupled during the period named; indeed, so satisfactory has been the result that a large extent of adjoining land has been similarly planted, or altogether, I think, about 40 acres.

The favourite Apple for the purpose is Bramley's Seedling on the English Crab stock—not on so-called Crab stocks raised

from the pips of cider Apples. The trees are in the best of health, free from canker and other ailment, and combine sturdiness with vigour and productiveness. Some rows of other varieties were planted in the first instance, but the appearance of the trees shows in an unmistakable manner the superiority of the former, and the later plantation is either all "Bramleys," or all that could be had, with an outside row of Damsons.

I do not remember a more remarkable sight than sitting in a "trap" and looking over the hedge across the established plantation. The Apple trees were planted 30 feet apart—standards on 6-foot stems—but none of them was visible, but only the heads of the trees, 12 to 15 feet in diameter, just above what was like a waving sea of green—the Osiers. These were quite 6 feet high, and not a blank nor faulty place to be seen. Moreover they appeared to grow practically as well close up to the stems of the trees as between the rows. There might in places be a suspicion of thinness immediately under the trees, but there was perhaps as much of fancy as fact in the idea; and what was conclusive was the broad and important lesson conveyed, that the Osiers did not deprive the Apples of nutriment, nor the Apples the Osiers. On the contrary, it is almost certain that the latter benefited the former, and this in two or three respects. First by abstracting moisture which otherwise might have been in excess for the Apples. Secondly, by the myriads of leaves falling annually from the forest of stems, forming a stratum of humus on the clayey soil—exactly what such soil needs. And thirdly, by sheltering the trunks of the Apples, which, in consequence, seem to swell more "kindly" than under full exposure. They bear the gloss of health that may be compared with the coat of a sleek animal.

The return to the land in the fall of leaves is evidently full compensation for whatever may be abstracted from the Apples by the Osiers. In all likelihood these soft pliable annual shoots take little out of the soil besides water, and leave the bulk of the phosphates, potash, and other mineral ingredients behind for the fruit trees. Be that as it may, these have obviously what they need, and nothing is added artificially. Trees in better health and bearing condition cannot well be imagined, and it is not conceivable that they could possibly be better if no Osiers had been grown among them, and it is generally believed would not be so good. The under crop costs next to nothing to grow, never fails, pays a good rent for the land, with a substantial margin of profit on that crop alone, apart from the Apples. And what about these?

I have not inquired about those particular trees, but I have seen trees that were planted in good soil fifteen years ago, which have produced £2 worth of fruit each as their last gathered crop, and am credibly informed of others of even greater value; but I have seen sufficient without detailing supplied information for satisfying myself of the great value of this Nottinghamshire Apple as an orchard standard. It may possibly be too robust for bush culture, but the effects of dwarfing stocks in arresting its natural vigour remains to be proved, for until recently its introducer, Mr. Merryweather, has only worked it on the Crab. But there are bushes and bushes, and I suspect a big bush of Bramley bearing 15 to 20 pecks of fruit quite a possibility, and such bushes would suit me very well, as I have no faith in stunted pigmies for usefulness. There is plenty of room above ground for the branches to extend, and I like to see them laden with fruit higher than a man can reach rather than having to stoop down to gather it.

However, as a standard Apple Bramley's Seedling has proved its great value. Ten yards apart is close enough for planting in good soil. The trees have then room to develop under the influence of light and air, and thus become the most fruitful, while the crops can be gathered with facility. The fruit is large, colours fairly well, and is of the first quality when cooked, possessing some of the sprightliness of Dumelow's Seedling with the sweetness of the Blenheim Pippin.

The mention of the last-named Apple reminds me of much

praise that has been showered on it in the *Times* and elsewhere. I say nothing against the quality of the fruit nor its appearance, but to recommend that this variety be largely planted for profit, and especially by persons who are neither owners of land nor of much money, is, I am convinced, very far from being safe and sound advice. I have planted trees of it and waited for the crops, also Bramley's Seedling, and were I going to plant a large orchard tomorrow for profit I would rather pay half a crown each for good trees of the latter than have equally good examples of the former as a gift if they were also planted gratuitously. I am so hardened by stern realities as to pay little heed to persons who write about fruit, yet have not been trained in the school of experience; but when I find a gardener, who is nothing if not practical, who advocates the planting of this slow and shy bearing Apple for profit because, forsooth, it headed the poll in the number of selections at the Chiswick Conference, and when he has condemned the variety to me because of its shyness, and agreed that I acted wisely in excluding it from a short list of sorts for cottagers and small holders of land in the essay above noticed, I am tempted to put him into a very awkward corner in which he would, perhaps, not be very comfortable, but I refrain at present.

The mere position on the poll, unless the ages of varieties are taken into account, is not only worthless as an indication of merit, but misleading, because, obviously trees of those sorts which have become popular favourites must have increased in proportion with the period of propagation, and in the case of the Blenheim this is at least seventy years. Judged by that fair test the Blenheim is in a false position, and this practical gardener may as well say that because sparrows are more numerous than geese the former are the better birds, and because donkeys are more plentiful than mules these latter are inferior, therefore he will praise the donkeys.

If a national vote were taken for determining the best orchard standard Apples possibly the Blenheim would head the list, and Warner's King would poll far higher than Bramley's Seedling; but if all the voters had grown the three together over a period of twenty years, and noted the value of the crops, I have not the slightest doubt that the Nottinghamshire Apple would head the poll by a very long way; yet only two dishes of it were staged at the Chiswick Conference in 1883 against 115 of the Blenheim. What value can a poll be under such condition for denoting the relative merits of two varieties when not one voter out of a hundred has grown them both for comparison? I can understand a writer whose experience in fruit culture is limited founding an argument on such a false basis, but I cannot understand a gardener doing so who claims a position as an experienced grower of hardy fruit. Perhaps it may be well to add that the trial above suggested is not hypothetical, but an accomplished fact, and the much-praised Blenheim shows to great disadvantage, as judged by the results attained under equal conditions.—J. WRIGHT.

FLOWER CULTURE FOR PROFIT.

CHRYSANTHEMUMS.

MANY growers of Chrysanthemums for sale had a somewhat unfortunate experience with the bulk of their stock of plants during the past season, and may perhaps feel disposed to dispute the fact of their being classed as profitable in any case. Owing to the abundance of outdoor flowers—for Chrysanthemums were never better or more plentiful in the open than in the autumn of 1889, as well as the great increase in the number of growers—ordinarily grown plants did not pay after the end of October; it was quite useless to send them to the markets in fact. When the pot plants of Madame Desgrange and C. Wermig were first well into flower there was a fairly brisk demand for them, somewhere about 18s. per dozen bunches, and in some instances a still better price was forthcoming. A bunch in our case, and which I believe to be the rule, consists of one dozen good blooms or sprays, and this number or more ought to be forthcoming from every plant in a 9-inch pot. Even if the blooms from each plant on an average only realised 1s., this still leaves a good margin in favour of the

cultivator. When, however, the price for either white or coloured varieties drops to 3s., or even less per dozen, with commission and carriage to be deducted, the balance is all against the grower, and rather than risk a similar recurrence of low prices the prudent man will considerably alter his practice—that is to say, will attempt to grow what really will pay.

The question naturally arises, What will prove profitable? and this I can answer satisfactorily. Instead of growing large numbers of the early and midseason free-flowering varieties in the old fashion I would advise that only a moderate number of the following be grown—viz., Mrs. Cullingford, dwarf, early white; Madame Desgrange, yellowish white, early; G. Wermig, a yellow sport from the latter; Mrs. Hawkins, bronzy yellow, early; W. Holmes, bright red, an early Cullingfordi; La Vierge, dwarf, pure white, second early; Lady Selborne, tall grower, pure white, second early; Sœur Melanie, a miniature Elaine; and the last named be grown principally for bunching. Now is a good time to place sound strong cuttings of these in ordinary Pelargonium boxes, and with the aid of gentle heat all will root quickly. When well rooted they ought to be pinched back, and when breaking afresh be placed singly into 3-inch or rather larger pots, all being strong stocky plants. Keep the plants growing in a pit or frame near the glass, stop once more, and in the course of about ten days the bulk may be shifted direct into 9-inch or somewhat larger pots, in which size they are to flower. Being given a somewhat large shift water must be sparingly given at first, but when once the soil is well filled with roots the soil ought never to become really dry. Turn out the plants into a sunny yet fairly sheltered spot towards the end of May, set the pots, or partially plunging them in a bed of ashes. Further cultural details consist merely in placing a stake to each plant, the principal growth being loosely fastened to these. Being well attended to, given a little weak liquid manure occasionally after branching has commenced, and abundance when the buds are showing, fine branching heads of bloom will be produced, and which early housing will preserve from early frosts and heavy rainfall. Too frequent stopping is the greatest blunder that can be made with this early batch of plants, a few strong early formed shoots producing much more bloom than considerably larger plants obtained by pinching back several times. Bushy plants in small pots also sell readily, realising in country markets 12s. to 18s. per dozen, and the varieties named are among the best that can be grown for that purpose.

During November and the early part of December the demand for Chrysanthemums in bunches is, as I have previously pointed out, of a very limited character. It is unwise therefore to grow many of these, though it is advisable not to wholly discard the system. The best for bunching at this date are Elaine, Mons. Astorg, greyish white; Fair Maid of Guernsey, pure white; Mons. Garnier, bronzy red; Cullingfordi, red; Elsie, creamy white; Peter the Great, yellow—all Japanese varieties and incurved; Mrs. G. Rundle, early white; Mrs. Dixon, yellow; and Jardin des Plantes, rich yellow—Japanese. Middle. Lacroix and others with twisted florets are sometimes grown for bunching, but they do not "take" so well as those with broader reflexed or incurved florets, as they travel badly, and to the uninitiated they present a somewhat withered appearance. This section ought to be grown much as advised in the case of the earlier varieties, but if thought desirable may well be stopped a third time, and be flowered in 12-inch pots or planted out in the open, and potted up in September. The flowers will be much finer and sell far more readily if disbudding is resorted to, not, however, with the intention of growing a few blooms only, but rather with the view of securing one good bloom instead of several small ones on each terminal shoot. The former we got rid of readily last season at 2s. per dozen blooms, and from some of the plants we cut as many as three dozen at that price at a time when bunching flowers could hardly be given away.

Last season it came as a revelation to many, though it was not new to me, that specimen blooms, not necessarily those which would gain premier prizes, but only ordinarily good samples, could be disposed of in most provincial towns at remunerative prices, and at a rapid rate. In 1888 we found specimen blooms sold well in towns generally, and at still better prices in London, and the demand was quite as brisk last November and December. The prices range from 4s. to 6s. per dozen wholesale, and plenty were retailed at more than double the latter price. Seeing that a plant grown in a 9-inch, or rather larger pot, 12-inch pots suiting the very strongest growers, is capable of producing from six to a dozen good blooms, it requires no great stretch of imagination to detect the profit attached to this method of culture that thus results. As a rule the Japanese varieties are in most demand, though occasionally a few fine incurved flowers work in well. We get much the same price for nearly all the specimen blooms, though there is no

doubt the white, yellow, and red shades are the most popular either for ladies' wear or for table decoration. Some of the most profitable are Fair Maid of Guernsey, Elaine, M. Astorg, Mdle. Lacroix, M. J. Pigny, Avalanche, and Mrs. J. Wright, all nearly or quite white; Peter the Great, Thunberg, Mr. H. Cannell, and Golden Dragon, yellow; J. Délaux, dark red; Jupiter, bright red; Carew Underwood, rosy bronze; Japonaise, orange; Hiver Fleuri, white and rose; Duchess of Albany, orange and red; E. Molyneux, crimson, gold reverse; Comte de Germiny, yellow, striped crimson brown; and Valle d'Andorre, chestnut red.—M. H.

HARDY SHRUBS FOR FORCING.

DEUTZIA GRACILIS.

DEUTZIA GRACILIS is unquestionably one of the most useful plants we possess for flowering during the winter and spring months for conservatory and other forms of decoration. The best method of raising a stock of plants for forcing purposes is by cuttings of young growing shoots taken off after flowering. The shoots should be soft, about 2 inches long, and if cut to a joint every one will root when inserted in sandy soil and plunged in brisk heat in the propagating frame. It is necessary to keep them close and shaded from the sun until they are rooted. As soon as this takes place gradually harden them by exposure to light and air. Before they become rootbound they should be transplanted about 2 inches apart in shallow boxes. A suitable compost is formed of equal parts of leaf mould and old soil from the potting shed, in which bulbs or other plants may have been growing for a short time. A good watering will be necessary, and as soon as they commence growth the point of the plant may be removed to induce them to branch. If the cuttings are rooted early in the season they may be pinched when they have grown about 2 inches in length. As soon as the young plants are growing freely in the boxes harden them gradually, so that they can be removed to an intermediate temperature, where they may remain until May, when they may be again hardened, grown in cold frames, and prepared for planting out the first week in June.

The position selected outside must be an open one, where they will be exposed to the sun. The soil in which they are planted must be well manured, and a liberal quantity of leaf mould stirred into the surface as well. The last is not really necessary, but where it can be practised the plants grow more rapidly than when the ground is manured in the ordinary way. If the plants are to be lifted as soon as they are large enough for 5 and 6-inch pots plant them 6 inches apart in rows 1 foot asunder. When removed from the box the method we have found best is to cut them out with a knife, so that each plant has a ball of soil attached to its roots 2 inches square. It may be necessary to water them after they are first placed out, and if the surface can be covered with leaf mould or other material to arrest evaporation so much the better. Failing this the hoe should be frequently used amongst them until they show signs of vigorous growth. In the following February cut them back level with the ground, which will induce them to push up strongly, and this must be repeated until they are large enough for lifting and potting.

Where there is no convenience for raising and growing Deutzias for a time under glass they can be treated throughout as hardy plants. Insert cuttings of growing shoots under handlights or a bellglass in a shady position in light sandy soil early in August. If well watered and the glass placed over them the only attention they will need afterwards is to water them if the soil becomes dry. If in a shady position they will be rooted before they need attention in this respect. When they are rooted gradually harden and ripen them. During showery weather towards the end of March or April they should be planted out as advised for those raised and grown in boxes. If ground is an object, dibble them in thickly together so that they are not crowded, and transplant them the following season. However carefully the work may be done the young plants receive a slight check, and they do not make such satisfactory progress as when planted out permanently at the first.

Lift the plants when they are large enough towards the end of September, or early in the following month. If plenty of leaf mould has been stirred into the soil the plants will be secured with plenty of fibrous roots. These should be reduced carefully according to the pots in which they are to be placed, employing good loam, one-seventh of decayed manure, and a little sand. Press the soil firmly into the pot, and one crock at the base will be ample. Stand the plants in a shady position for a few days, and syringe them freely two or three times during the day. This will prevent the foliage flagging, and roots will commence forming in a short time. Plunge the pots in a sunny position. If the surface of the

soil is covered with the plunging material, and this is kept moist, no water will be needed at their roots beyond the small quantity that finds its way to them by syringing, which may be continued until the plants will bear full exposure without flagging. These lifted early and given the treatment described will have their pots nearly full of roots by the time frost destroys their foliage. We have used them for late flowering in spring without signs of injury, but we do not advise this course to be practised.

Hundreds are ruined that are annually purchased, potted, and forced, during the winter or spring months. Plants that are lifted after the foliage falls, or when approaching that stage, potted and then forced, may flower freely enough, but they never make any but the most puny growth the following season. In many cases it is not stronger than that of plants the first season they are raised from cuttings. To have Deutzias in the best possible condition for forcing, lift them early, and prune closely back after the foliage has fallen, and then grow them one year in pots. Pruning may be done at any time during the winter, and the pots can be plunged in cold frames. This will induce early growth, and consequently early ripening in autumn. The plants may be hardened so that they can be grown outside from the end of May. When the pots are full of roots weak stimulants may with advantage be given, and the result will be stout shoots from 1 foot to 18 inches in length. After they have flowered they should be cut back, allowed to start again into growth, and then placed into pots 2 inches larger. If forced moderately early in the season they must be started again into growth, and grown under glass until they can be hardened, and the weather is sufficiently genial for placing them outside. Large bushes with short twiggy growths flower profusely, and are produced by the removal of decaying flowers only. Pruning in this case must not be practised. But, however well these may look, we prefer to prune them close back after flowering. Clean growths, varying from 2 to 3 feet in length and profusely flowered, are much more graceful and attractive for decorative purposes than those crowded with short growths and old wood.

To keep a stock for forcing in the best possible condition Deutzias must be well cared for after flowering and encouraged to make their growth for a time indoors. When turned outside, or even removed from structures in which they have flowered to others that are cold and draughty, they are seriously checked and refuse to grow; in fact, they soon become stunted and useless. When subject to early flowering, however good the treatment may be, they will, after their pots become crowded with roots, decline to grow luxuriantly. When well established specimens are in this condition they should not be thrown out as worthless, for one year's rest is ample to restore them to vigour. After flowering cut them back as usual, and if they have been forced early they will naturally ripen early, and may, about the middle of August, in some cases earlier, even in July, be turned out and their roots reduced one-third. Treat them afterwards in the same way as young plants. While growing, abundance of water is necessary; in fact, in no stage, not even while at rest, should Deutzias be allowed to become dry. On the other hand they must not be over-watered after they are potted until they are rooting freely in the new compost.—N. G.

EMIGRATION OF GARDENERS.

(Continued from page 125.)

FRUIT.—Strawberries succeed famously, especially in Long Island. They, however, are not given any particular culture. When in full season they may be had at 6 cents per quart. When first coming in from Florida, as they do in March, the price is 1 dollar per quart, but they are only Strawberries in name. Gooseberries do not succeed, or Black Currants. Red and White Currants thrive tolerably in shady places. Raspberries do capitally, also Blackberries, which are grown similarly to Raspberries—i.e., cutting out the old and weak wood, the fruiting canes being cut back about half their length, and four or five of the strongest reserved to each stake, the stools are 5 feet apart. The fruit is very large, and very much esteemed for dessert, largely used also like Strawberries, with cream. They are grown in fields by the acre.

Apples are much the same in Maine, but are finer in colour, with a corresponding lack of juice. Pears do well, also Cherries, but not Plums; they are not good only in the hills in New York State and elsewhere.

Peaches do splendidly. The trees are half-standards, the treatment being briefly to well thin the old wood, leaving the young, every year providing for itself. Maiden trees are planted in rows about 20 feet apart, and 10 to 12 feet asunder in the rows, ground cropped with Sweet Corn until the trees commence bearing. A few

fruits are produced in the third year; the trees are in full crop at the fifth, and after five years bearing the trees are replaced, or are seldom left over a dozen years on account of the yellows and the susceptibility to red spider. They are grown by the 100 acre in Delaware. Bradley's fertiliser is used extensively in Peach culture, a good sprinkling around each tree before rain. In some years good fruit can be purchased at two for 1 cent.

Grapes are grown in vineyards about St. Louis, Missouri, on espaliers, three wires about 18 inches apart. Six feet is allowed between the rows or trellises. The Vines are mostly trained or treated on the spur system, but the rod also obtains. The fruit is mostly used for wine making. In New York State at the foot of Catskill Mountains on the banks of the Hudson river, Grapes are grown on the single rod system—i.e., as cordons. The shoots are stopped two joints beyond the fruit, and all laterals are kept closely pinched until the fruit is set, after which all growth is allowed to remain so as to prevent the sun scorching the berries, thinning out the growths only where they are very much crowded. Concord is the favourite Grape grown for dessert, it being a black oval kind. Manure is applied in the fall and forked in then. Fertilisers are applied during growth before rain. After the Grapes are cut the knife is brought into play, cutting away all useless wood, so as to let in sun and air for the perfecting of the wood and buds. When the leaves begin to turn yellow the current year's wood is cut back, the final pruning being done early in spring, or a month to six weeks before activity commences. In spur-pruning three or four buds are left, whilst rods are pruned to a plump bud on well-ripened wood.

Cultivators in the United States employ artificial manures largely, the object being to get the crops up and growing away quickly, so that they may be less susceptible of injury from insect pests, and better able to contend with the trying ordeal of the heat and drought. Our informant says the Maine farmer formed his own artificial manure as follows:—Taking care of all the bones, they were bruised on a hard substance with a hammer, or half-inch bones were purchased. These were saturated with urine, placing in a tub or hole in the ground in a dry place and kept dry, with wood ashes in equal proportion to the bones, or 1 bushel half-inch bones saturated with urine and 1 bushel wood ashes, the latter being also saturated with urine, covering with dry earth 2 inches thick. In about three weeks the bones are dissolved, when a bushel of pigeon or fowl dung is added, the whole being well incorporated, which form a paste-like mass, in which state it is placed in a dry place, and by spring it forms a hard mass, which, however, breaks up readily, and being fine is readily applied to any crop requiring a stimulus, a good handful being sufficient for a couple of square yards.

In concluding these notes I desire to state that our prompter strongly advises those who are doing well here to leave it alone. They may do as well, perhaps better, in the United States as far as money is concerned, but it will be had at a sacrifice of home enjoyments, and of trying conditions of climate to which all do not become acclimatised satisfactorily to themselves. Those that cannot from incapacity, lack of energy and physical force do here will not succeed there, it being no uncommon occurrence to find numbers picking up a precarious existence in the Atlantic seaports, whose one cry is to get sufficient money to pay their return passage to England. "A man," he says, "that cannot on occasion work his way among civilised communities by land or sea has no claim to that designation, being little better than an old woman."—UTILITARIAN.

PLANT FOOD.

(Continued from page 104.)

It will readily be seen that a good general manure ought to be composed of material which will yield ammonia and phosphoric acid in the largest proportion, and with a less amount of potash and lime. It is at this point that the difference between farming and gardening practice is most pronounced, and I think not in favour of the latter. The gardener purchases a manure, necessarily expensive, and applies it to all kinds of crops. The farmer, on the other hand, if he purchase a special manure, selects one which exactly suits his crop. If for Turnips, a phosphatic one with a good per-centage of ammonia. If for Beans, then a potassic compound is chosen. Or, he may, by the application of a simple dressing of nitrate to his Wheat or hay, increase the crop by 50 per cent. at a small outlay. But I think in most gardens manuring might be much simplified; for if in good heart there ought to be a sufficient quantity of potash to serve any crop in gardens. A dressing of quicklime will do much to set this free, as well as form a corrective to those acids which cause sourness, while the texture of the soil is sure to be improved. But even if quicklime is not applied, I

incline to believe (for on this point I can only speak from results, unconfirmed by science) that the employment of superphosphates, or one or other of the materials which supply ammonia, will of themselves set free sufficient potash for the need of crops. If that be so, gardeners may safely employ for garden use either superphosphate of lime or ground phosphates, to which, if required, nitrate of soda or sulphate of ammonia may be added, either at the time of application or some time thereafter. Either kind of manure is best applied as a surface dressing, and the time to select for application is while the ground is wet. Superphosphate, especially when newly made, destroys every bit of vegetable life it comes in contact with; consequently care is necessary to sow on the soil alone, though during wet weather less harm follows, as the rain washes the foliage clean before mischief ensues. The action of superphosphate is greatly quickened when applied whilst the ground is wet, and when rain follows its application. The moisture in the soil and atmosphere causes a quickened root action, and the more soluble of the phosphates are at once brought into contact with these young roots, with the result that immediate and continued benefit follows.

It always seems to me that there is a tendency to treat chemical manures in a mechanical manner—just so much to be given at a particular time, and leave the rest to Nature. Now, it is just possible and very probable that a dressing of manure applied in the manner just noted will put a plant into a condition ready to receive a further supply. The action of superphosphate in particular is to increase the number of active feeding roots, and I have many times been interested to watch the rapidity with which new roots come upwards to the surfacing on potted plants, spreading over, and quickly getting into contact with every little piece of it. Much the same thing occurs in the case of inside borders, which are regularly watered at short intervals. The tips of the roots protrude through the surface, and no doubt enjoy themselves very much. Of course, it is very necessary to exercise judgment as to when to leave off manuring, as also to take into consideration the animal manure which the crop may have at command. In the case of Celery, for instance, which is planted in soil with the addition of 2 inches or more of good cow manure close beneath the roots, the continued application of either superphosphate or of ammonia would simply result in the loss of the crop during a moderately severe winter, while a dressing not later than midsummer would have the effect of quickening growth without any danger of bad effects when growth ought to have ceased. Much the same remark would apply with regard to Onions which are grown for keeping; but if we want either Celery or Onions of a large size rapidly, without taking into account the question of keeping, then repeated surfacings is the best thing to do. This brings us next to consider the part of the plant we wish to use, and the best method of manuring in order to get the best results in each case. Both Celery and Onions are biennials, and the life work we wish them to fulfil is simply to make the most of their first year. The same remark applies to Turnips, Carrots, Beetroots, and Parsnips. We endeavour to cram them with carbohydrates, and find a light open soil enriched with phosphates and kept duly moist gives the best results. Potatoes represent a different class altogether. Like Jerusalem Artichokes, and Dahlias among flowers, the plant at the same time it is endeavouring to reach its highest destiny—the production of flowers and seeds—is also forming an underground stem with buds to carry its life work on in the succeeding year. In ordinary circumstances, to manure highly for these crops is to defeat the promotion of these underground stems. In each case we secure a magnificent top growth with flowers, fine and in abundance in the case of the Dahlia, but the tubers are sure to be small, and in the case of the vegetables possibly not abundant. You see, if we wanted fine top growth exclusively nitrogenous manures would be the very thing; but in order to get what we do want just sufficient nitrogenous manures to give the plant a robust start must be employed, and a manure of a potassic nature, or one that will bring latent potash into working order, be the predominating substance; and so with Peas and other legumes. A nitrogenous manure will form a magnificent crop of haulm, but in order to secure flowers and Peas potash is absolutely necessary. In our own case these crops are never directly manured, but if manure were needed it would be applied of a kind either to free potash or to yield it directly.

I think it is no uncommon occurrence that the particular elements wanting during rapid growth in the summer months is not so much any chemical or animal manures, but that wonderful combination of oxygen and hydrogen called water. The mere fact that from 75 to 95 per cent. of the structure of the plant is simply water, would of itself point to the absolute necessity of a moist soil to keep up a full supply during hot weather, but when it is further understood that water is the medium by which the gaseous agents and minerals are conveyed from the soil and throughout the plant economy, and that the roots themselves are absolutely

dependent for their activity and being on moisture, the necessity of water to crops in full swing will be emphasised. Speaking from experience, I believe the most important agent to successful outdoor culture during hot weather is an unlimited and easily accessible supply of water. No matter how fertile the soil may be, or however abundantly it may be supplied with fertilisers, an insufficiency of moisture will render these absolutely without any good effect. While, on the other hand, with abundance of water fertilisers may be used to the utmost extent, and the crops be benefited in the proportion they and water are employed. I will close this paper by drawing attention to a point long ago noted by chemists, and for a much longer period known and acted on by gardeners—viz., that young plants require very liberal treatment, quick healthy robust growth in the earlier stages laying the foundation for a big harvest.—B.

ODONTOGLOSSUM SCHROEDERIANUM.

SEVERAL orchidist friends have communicated with me respecting the above-named *Odontoglossum*, of which an illustration was incorporated in my notes on hybrid Orchids last week. Mr. F. Sander of St. Albans points out that Professor Reichenbach was undoubtedly wrong in regarding this as a natural hybrid, for it is as much entitled to be considered a true species as many others in the genus. Then came a pleasant letter from M. Godefroy-Lebeuf of Argenteuil, editor of *Le Jardin*, in which he says, "I do not know why Reichenbach regarded this as a hybrid. He could not ignore the locality it comes from, and what he says about the plant is obscure. *O. Schroederianum* is a true species, and it is found in places where *O. tripudians* and *O. Pescatorei* have never grown. I know the place, but it is a secret that I cannot divulge." The last statement about the locality in which the plant is found is interesting, and certainly appears to be conclusive as to its non-hybrid origin.

A GIGANTIC ORCHID.

MR. F. SANDER of St. Albans calls my attention to the following letter, which recently appeared in a London daily paper, from Mr. Arthur Keyser, Kuala Kubu, Ulu Selangor, Selangor, Straits Settlements:—"It may interest some of your readers to hear of one of the largest Orchids that has ever been seen in this country. I noticed it on a very high tree (Durian tree), while riding some fourteen miles from my house. It formed a complete circle round the tree. The Durian fruit being much valued by the Malays, I was not inclined to purchase the entire tree for the sake of the Orchid, and, therefore, perhaps did not obtain it in as good condition as I otherwise could have done. I ordered the plant to be scraped off, and brought to my garden. It is 7 feet 2 inches high, and 13½ feet across. It has seven spikes of flowers, the largest 8 feet 6 inches long. The flowers are dark brown spotted with yellow. It is very seldom that a European visits this part of the State. The Orchid does not get as much admiration as it deserves, the Malays thinking my appropriation of it a rather insane proceeding, as the blooms are not good to eat." It may be a species of *Grammatophyllum*.

CYPRIPEDIUM TESSELLATUM PORPHYREUM.

"ORCHID AMATEUR" writes for information respecting the above *Cypripedium*, and says, "I have heard or read that it is one of the most distinct in colour of the whole family." We reproduce the illustration (fig. 23) as a guide to the form of the flower, and we may add with regard to the colour that our correspondent has been rightly informed, for it is very remarkable. The hybrid was obtained from a *Cypripedium concolor* crossed with *C. barbatum*, the floral form showing the characters of the former, and the colour partakes of that of the latter parent. It is, however, a peculiarly rich purplish rose tint unequalled in its way by any other form in the genus, and it is strange that the deep tints of *C. barbatum* should have been brightened and enriched to such an extent by a cross with a yellow flowered species. In Messrs. B. S. Williams & Son's Nursery, Upper Holloway, this has been grown with much success, and a capital example was shown by that firm at the Royal Horticultural Society's meeting in October, 1888. It is surprising that it has never been included amongst the many

handsome *Cypripediums* represented in the "Orchid Album."—LEWIS CASTLE.

ORCHIDS AT Highbury, near Birmingham.

THE Right Hon. Joseph Chamberlain, M.P., on his arrival from the land of the Pharaohs, found a good display of his favourite flowers, for the Orchid show house is very gay just now, and there is a good sprinkling of bloom in the other houses. *Cattleyas* are numerous amongst them *Trianae alba*; *Warszewiczii delicata*, a fine form of *Trianae alba*; *Cattleya Corningii*, a pale variety of *Trianae*, with a blue lilac tint in the labellum. *Oncidium splendidum* is very fine, so also are *Dendrobiums Ainsworthii*, *Leechianum*, and *Pierardi latifolium*, and *Odontoglossum Edwardi*. *Cœlogyne Lemoniana* is a charming Orchid, of closer habit, and a little smaller in the flowers than *C. cristata*, with a bright lemon blotch in the labellum; *Phalanopsis Stuartiana*, is distinct; *Odontoglossum Roezli album*, and a fine variety of *Roezli*, and *Acineta Barkeri* are

FIG. 23.—CYPRIPEDIUM TESSELLATUM PORPHYREUM.

amongst those in flower. Mr. Woodfield has the Orchids well in hand, and plenty of bloom will now be the order of the day.—D. S. H.

CÆLOGYNE CRISTATA.

LARGE pans frequently become crowded with pseudo-bulbs in the centre to such an extent that these rarely develop to a size strong enough to flower profusely. When plants are in this condition and it is not desirable to break them up the only course is to thin them. It may be necessary to remove a few old pseudo-bulbs so that small pieces can be cut out, being careful not to injure the roots of those remaining. The holes should be filled with fibry peat, and the leads carefully drawn from where they are crowded and pegged over the vacant places. At the end of one year the pan will be covered with large pseudo-bulbs. It is surprising what a stock of plants can be raised by this method in a few years. Large specimens judiciously thinned every second or third year can be kept in good condition, and will flower freely if the pseudo-bulbs are well grown and matured.

The growths will be small the first year, but they will develop to a fair size in the second, and soon make good flowering plants. All the best pieces should be placed in pans and pots by themselves. Those with no prominent leads may be pegged on the surface of pots or pans nearly filled with crocks. They should be given very little material in the first season until they are established. Healthy fresh pieces with leads should have the pots about one-third filled with drainage. The pseudo-bulbs must not be buried in the compost; their rhizomes should be pegged on the surface, and after they commence growing place a little living sphagnum moss on the surface. *Cœlogyne*s do well in fibry peat and portions of charcoal. For a long time we have used moss only on

the surface. Care is necessary not to give too much water at first. If the compost is rendered too wet, either by the syringe or watering, puny growth only will result.

ODONTOGLOSSUMS.

Where these have been kept in a temperature at night of 50° to 55°, some of those that have flowered will display signs of growth. If these were potted last year in fibry peat with a layer of living moss on the surface, they will only need top-dressing at the present time. It is best to do this work before fresh roots issue from the base of the pseudo-bulbs. The moss should be carefully removed from amongst the roots, and fibry peat supplied. A little living sphagnum may be placed in patches amongst the peat, and if encouraged to grow will soon spread over the surface. If not, after growth and root activity has commenced in earnest a few good leads will quickly establish themselves amongst the peat. When the plants are top-dressed early there is no fear of breaking tender young roots, and when they commence growing they enter the fresh compost on the surface freely.

LARGE POTS.

For *Odontoglossums* large pots are not needed. Plants with large pseudo-bulbs can be grown in 6-inch pots, unless there are three or four strong leads, when larger pots are required. These plants do not succeed so well when they have a mass of unoccupied soil about their roots. It is apt to become too wet, and the roots perish in consequence. We have tried potting the plants without disturbing their roots, but this practice is not a safe one; a quantity of decayed material accumulates about them, which quickly results unsatisfactorily. No injury follows this method when the plants have been imported and are started in small pots, they can be repotted safely; in fact, it often has to be done during the season of growth. It is surprising how long these plants can be kept in the small pots in which they have been started. They will make strong growths and large pseudo-bulbs before it is necessary to place them into larger pots. We are firmly convinced that more harm results from growing these plants in pots too large for them than from keeping them in those that are too small.

CYPRIPEDIUMS.

Plants imported in autumn are a long time before they form roots and start into growth. We have tried placing them in pots directly they arrive and suspending them roots upwards in the stove or other moist structures, and have found the latter treatment the most satisfactory. Plants subjected to this treatment for the past two months show no signs yet of rooting and growing. Although they have been freely syringed, they have remained almost the same in appearance. During the past week they have improved in freshness, and will not be long before they commence forming roots. Plants in this condition should have a little living moss bound about the roots. This will increase the amount of moisture about them, and directly they commence rooting they should be placed in pots according to their size. Peat fibre, moss, and a little charcoal, or crocks, form a good compost for them at first. The pots used should be about half filled with drainage and the plants slightly elevated above the surface.—ORCHID GROWER.

L'ORCHIDÉENNE.

THE monthly meeting of the above Society took place on the 9th inst. in the central gallery at L'Horticulture Internationale, Park Leopold, Brussels. The Orchids exhibited were very numerous, and exceptionally good for this time of the year. There was a large attendance of amateurs, and the fine weather in the afternoon brought hundreds of visitors to admire the display. Of the Committee members the following were present:—Messrs. J. Hye-Leysen, Wallaert, Massange de Louvrex, Lübbers, Lallemand, Miteau, Rodigas, L. Linden, Secretary du Trien de Terdonk, Treasurer.

M. G. Warocqué staged a large group, foremost among them being a well-flowered specimen of *Lælia anceps* bearing over 100 blooms; a new *Cypripedium* named *Warocqueanum*, which has flowered with a number of imported plants bought as *C. præstans*, the colour of the petals being especially fine; a splendidly flowered plant of the beautiful *Odontoglossum Pescatorei* Lindeni, of which he is the only possessor; and *Odontoglossum crispum sulphureum*, a fine form, very rich in colour. M. J. Hye-Leysen exhibited a group of choice Orchids, several of which were certificated, including a superb form of *Lælia anceps alba*, named Lindeni, *Odontoglossum Wilckeanum albens*, and a beautiful variety of *Cattleya Trianae*. M. Wallaert sent *Dendrochilum glumaceum validum*, shown for the first time, very distinct and beautiful; also a fine

variety of *Cattleya Trianae*, and *Cypripedium villosum albo-marginatum*. M. le Comte de Bonsies contributed a well-flowered specimen of *Cattleya Trianae*, a beautiful dark variety. M. Van Imschoot sent a well-flowered plant of *Cattleya speciosissima*, and a flower of a *Lycaste*, variety unknown, apparently of the *L. plana* type. M. Vervæet staged a number of exquisitely fine varieties of *Cattleya Trianae*; also *Cypripedium Barteti*, and *Godseffianum*, the latter being particularly good. M. Miteau sent a well-flowered plant of *Cattleya Trianae* Baillonville, several plants of *Cypripedium Boxalli* varieties, and *Cypripedium barbatum Veitchi*, a beautiful hybrid; and several fine varieties of *Odontoglossum crispum*. M. Linden contributed a large and interesting group; the most noteworthy were *Cattleya Trianae Hyeana*, an excellent variety, with large well-shaped blooms of a rich colour; also a well-flowered specimen of the paler variety, *Cattleya Trianae pallida*; *Odontoglossum Rossi maximum*, a similar variety to the one shown by Madame Gibez at the last meeting, the flowers being of exceptional size and superb colour; a large specimen of *Maxillaria luteo alba*; *Cattleya Percivalliana*, a superb variety of *Odontoglossum crispum*, and others.

The following awards were made by the Committee:—Diploma of honour of the first class to M. G. Warocqué for *Cypripedium Warocqueanum*, to M. Wallaert for *Dendrochilum glumaceum validum*, to M. J. Hye-Leysen for *Lælia anceps Lindeni*. Certificates of merit of the first class to M. G. Warocqué for *Odontoglossum Pescatorei Lindeni*, to M. Linden for *Odontoglossum Rossi maximum*, to M. J. H. Leysen for *Odontoglossum Wilckeanum albens*, to M. Linden for *Dendrobium Wardianum giganteum*, to M. Linden for *Cattleya Trianae Hyeana*, to M. Vervæet for *Cypripedium Godseffianum*, to M. Wallaert for *Cypripedium villosum albo-marginatum*, to M. J. Hye-Leysen for *Odontoglossum crispum guttatum*, to M. Miteau for *Cattleya Trianae Baillonville*, to M. Wallaert for *Cattleya Trianae*, to M. J. Hye-Leysen for *Cattleya Trianae*, to M. Vervæet for *Cattleya Trianae*. Certificates of merit of the second class to M. G. Warocqué for *Odontoglossum crispum sulphureum*, to M. J. Hye-Leysen for *Odontoglossum Mulus*, to M. Linden for *Odontoglossum crispum*, to M. Vervæet for *Cypripedium Barteti*, to M. Miteau for *Cypripedium barbata Veitchi*, to M. J. Hye-Leysen for *Cypripedium lævigatum platytænium*, to M. Linden for *Cattleya Trianae pallida*, to M. Vervæet for *Cattleya Trianae*, and to M. Warocqué for *Cœlogyne Lemoniana*. A first class cultural certificate was awarded to M. G. Warocqué for *Lælia anceps*. Second-class cultural certificates were awarded to M. Miteau for *Cypripedium Boxalli*, to M. Linden for *Maxillaria luteo alba*.—BRUSSELS CORRESPONDENT.

INSECTS OF THE FLOWER GARDEN.

THE beetle tribes offer a great contrast to the butterflies and moths, some species of which have been described in previous articles. In their condition as beetles many of them are of dull colours, and disinclined to exhibit themselves to view, though some few species make themselves conspicuous in broad daylight. But while they are in the larval state most of them are hidden from observation, a large number being under the earth or secreted in plants. At this time of the year, when our flower beds and borders are turned over in preparation for another season, beetles are familiar objects to the gardener, and usually recognised as such. Should their larvæ be unearthed, however, a doubt often arises as to what they will "turn to," and they receive the vague name of "grubs." Said I to a friend who was making devastation amongst beetles by the free use of a hoe. "Take care what you are about, it is very unlucky to kill a sunshiner." He acknowledged that he was ignorant of what a "sunshiner" was, and I explained that this name was formerly given more particularly to the small brilliant beetles of the genus *Amara*, which frequently come in the gardener's way, therefore are likely to be killed. The supposition was that if this happened a storm of wind or rain might be looked for. Many other beetles besides the *Amarae* in that group might be called sunshiners also, as they have often bright colours. There is seldom need to destroy them, since their proceedings are not such as to make them injurious, the bulk of them being of carnivorous habit.

Certainly there have been some instances recorded lately in which predatory or carnivorous beetles seem to have gone "off their heads," and leaving their wonted food have attacked such a fruit as the Strawberry, and also the succulent roots or underground stems of plants. One of these much complained of was popularly called "black Jack," a dark beetle of the genus *Harpalus*, probably. Other species have been proved to be similarly transgressors, and as their jaws are powerful for their size they can do some mischief. I am inclined to think that the reason of this,

eccentricity is a failure of their natural food, which drives them to a substitute. If kept in boxes they will eat greedily cooked meat, and for want of other food will attack and devour each other. The ground beetles, as we entitle these carnivorous species taken as a group, kill many small caterpillars, also various insects in the pupa state and grubs of some of their relatives that are root-eaters. A pretty and conspicuous species common in France is there known by the name of *Le Jardinier* (in science it is *Carabus auratus*), and it is the special foe of such species as the cockchafer and the rose beetle. Its near ally the violet ground beetle (*C. violaceus*) is often brought up by the operation of digging beds, and it should always be spared, for though it buries during the day, after dark it comes forth and hunts other insects. Several of the ground beetles select for their food small snails and slugs, destroying in their career a good number of these, for they appear in autumn, and after hibernation come forth early in the year and feed again. It is doubtful whether in the grub or larval state they all are carnivorous; some of them are known to resort to heaps of dead leaves, decaying stems or fungi, and so they probably help to remove what might be offensive, or convert it into nutritive matter for the soil. In size the ground beetles vary from the *Carabus*, a full inch long, to a small *Amara*, hardly a quarter. Their colours are generally bright, though a few are dull green or black. Many species have the wing-cases covered with small punctures or rows of narrow streaks.

From the ground or carnivorous beetles we pass to the *Necrophage*, or "carrion-eaters," so-called from the habits of a majority of the species. The burying beetles, which occupy themselves in the work of interring dead birds, small quadrupeds, frogs, &c., are a familiar instance of the group, but these seldom occur in the precincts of the flower garden. A funny little beetle, not bigger than a good-sized pin's head, which rejoices in the name of *Eumircus tarsatus*, occurs frequently amongst plants that have been kept through the winter in hotbeds, the larvæ feeding on vegetable or animal matter, but it does no harm. In colour the beetle is chestnut and black, downy, and with prominent eyes. Next we reach other tiny beetles, too well known to every gardener, and which also inflict annoyance upon persons who are inhaling the perfume of a beautiful nosegay, and who may chance to find that in sniffing at the flowers they have unawares drawn an insect into the nose. The beetles of the family *Nititulidæ* have flattened bodies, depressed heads, and short antennæ. Their shining aspect has given rise to the Latin name, nearly all being more or less glossy. They lurk amongst flowers, biting the petals, but their exceedingly small size, as compared with that of many beetles, renders the mischief they do less observable. Still, when a dozen or two are found hiding in one Rose blossom, their united operations cannot improve the flower. A very plentiful species is called *Meligethes æneus*. It is metallic or brassy, and creeps slowly out of the flower when it is shaken. Some kinds drop out, feigning death. While in the larval state these flower-lovers feed upon decaying substances, especially bark and wood.

A prominent member of the family known as the rove beetles, or cocktails, often crosses the garden path, being an object of dislike naturally, sometimes also of alarm. The rove beetles generally are, as their name implies, of wandering habit, and run briskly; they can fly, too, with speed, for they are provided with large wings. This particular species always indicates the appropriateness of the second name by the menacing way in which it raises the hinder part of body, at the same time opening its jaws. Should a stick be held towards one of these beetles it is not in the least frightened, but attempts to strike at this or any other object which may be directed towards it. In addition to its jaws the goerius has a means of defence at the tail, from which it can throw a fluid, the odour of which is as horrible as that of the skunk. In colour it is dull black, and from its repulsive aspect in some counties folks call it the "devil's coach-horse." Yet it is a useful insect, killing other insects of various sizes, and as a larva it is predatory as well, feeding not uncommonly upon small worms and slugs it is stated. Some very small relatives of this species, with the like propensity for ejecting a pungent liquid, often fly about our gardens on summer evenings and make wild dashes at the human eye. Should one enter, as they will, the pain is often intense for a time, due probably to this liquid.

We could hardly find two beetles offering a greater contrast in appearance than that just described, and the beautiful rose beetle or chafer (*Cetonia aurata*). Above the beetle is green shot with gold and marked with some whitish dots. Underneath the surface is bright copper. It has tolerably strong wings, and takes excursions in the sunshine, but it certainly commits some damage, being specially fond, as the name implies, of haunting the flowers of the Rose. Gardeners also tell me that they believe the rose beetle has a partiality for the blossom of the Strawberry, and biting them

when expanding reduces the yield of fruit in some places. The fat clumsy grub or larva of this beetle feeds on rotten wood, but from the profusion in which I once met with the species in a market garden distant from trees, I think it possible that the food may occasionally be the roots of plants.—ENTOMOLOGIST.

JAM FACTORIES.

At the present time, when fruit tree planting is being pushed vigorously forward, something certainly should be done as a means of turning the industry to a profitable account. Many people with small means have been led to take to planting fruit trees as a means of increasing their income, and unless there are suitable jam factories for disposing of the fruit, I fear there will not be much profit for numbers of people who have been led to embark in the enterprise. As Mr. Wright truly says, growers must not rely upon Apples exclusively if they wish to reap reward, for if they do they certainly will not secure it. The small growers especially will find a difficulty in disposing of their fruit, but by establishing jam factories in suitable districts, so that the fruit could be delivered fresh within an easy radius, I believe that fruit growing may be made a source of profit for small growers as well as for others. As I have previously stated, this is no new idea, for we have what Lord Sudeley has done at Toddington before us, and he, I believe, was the pioneer. Others are following, such as Lord Coventry at Pershore, another at Evesham, and in our own immediate neighbourhood a large farmer has carried one on successfully for the past four or five years. He grows quantities of fruit, and also buys what others have to dispose of. And this is what is required in every district where fruit growing is likely to be taken up. I think if something of this kind could be carried out we should be opening up a profitable industry. As Mr. Wright says, we have the cheapest sugar in the world, and also the world for a market. The fruit could be preserved in a whole and fresh state, and people would know what they are buying. Of course it would have to be turned out at a cheap rate. The price of the fresh fruit would have to be governed by the market.

Strawberries, Gooseberries, Raspberries, and Currants would be the fruits to grow for this purpose, with Apples and Plums as top fruit if desired. Those growers who may be fortunate enough to reside within an easy distance of a factory would not be burdened with heavy railway rates. Care would have to be taken with the gathering of the fruit so that it could be delivered in a whole and fresh condition, Strawberries particularly so. If the fruit were forthcoming no doubt the factories would soon be established, as without the certainty of a full supply this would be useless. The same factories could also be used as agencies for buying up Apples. In many country districts cottagers find a difficulty in disposing of their Apples, even when good examples. But this should not be so, as they lose heart. The larger growers have the market more at their command, but even with these there may be a difficulty in disposing of their fruit in a raw state in the market a few years hence, so it behoves them to be on the look out. Small fruits so quickly perish after being ripe and gathered, that they are bound to be disposed of at some price, however small, or they would be useless. It is no new thing now, at least a year or two since, to see thousands of Damson trees full of fruit, and these allowed to drop and decay, as the market price would not pay even for the gathering.—A. YOUNG, *Abberley Hall Gardens, Stourport*.

NEW CLASS AT SUMMER SHOWS.

FRAMERS of prize schedules are often puzzled to discover something novel without in many instances adding seriously to the amount of prize money to be found. There is, and always will be, a certain amount of sameness about the best of shows, but much may be done by judiciously varying the arrangement of the various exhibits, and also by adding new classes occasionally, even if this necessitates cancelling some of the older ones. The cut flower classes are always among the most attractive of any, and it is among these where there is more scope for changes and improvements. My proposed addition to these is a very moderate one—viz., two classes at least for cut Begonias—one for double and the other single flowering varieties. If room or money is needed for these, then wipe out or reduce the number of those devoted to Verbenas, Marigolds, and even Asters, none of which are either so beautiful or popular as the Tuberous-rooted Begonia. Prizes are certainly provided for the latter, but seeing how very popular this class has become, and the ease with which everybody with a greenhouse can grow them, it ought to be the aim of framers of schedules to still further foster this love for a very useful flower.

For several seasons past Begonias in a cut state have been exhibited at all the principal West of England and other shows by Mr. B. R. Davis, nurserymen, Yeovil, and I have frequently noted how attractive these proved to numerous visitors. They are not arranged on clumsy

stands or trays with collars and other hideous accompaniments, but were neatly set out in shallow tin or zinc boxes holding water, and with a wire network strained across for supporting the flowers with their stems in the water. A groundwork of Maidenhair Fern fronds with a fringe of tiny Ferns in small pots gave the finish to a very pretty exhibit. There are really such a beautiful selection of these Begonias, both double and single, that it is comparatively an easy matter to bring a charming display together, and I should like to see prizes offered for an artistic exhibit of them as well as for a fixed number of varieties. Mr. Davis has also frequently exhibited hand and buttonhole bouquets composed entirely of Begonias and Fern, and very bright and attractive they look. Some of the varieties may easily be mistaken for Gardenias, Carnations, Picotees, and Eucharises, though without the scent unfortunately, and the delicate and rich shades of innumerable other varieties gives plenty of scope to an exhibitor. In conclusion, I venture to think that if classes were provided for cut Begonias these would soon be very popular with both exhibitors and visitors.—W. IGGULDEN.

☐ **EVENTS OF THE WEEK.**—The principal Society meetings during the week are the following:—The Royal Society Feb. 20th at 4.30 P.M., and the Linnæan Society the same day at 8 P.M.; the Royal Botanic Society on Feb. 22nd at 3.45 P.M., the Royal Geographical Society on Feb. 24th at 8.30 P.M., and the Society of Arts at 8 P.M. on Feb. 26th.

— **A FURTHER** official communication respecting the GREAT INTERNATIONAL HORTICULTURAL EXHIBITION AT BERLIN has been issued, from which we gather that additional special prizes have been offered, including one from Her Majesty the Empress of Germany, and that several prominent German horticulturists will participate in furnishing the Exhibition. The great French firm Vilmorin Andrieux and Co. will be represented, and among British horticulturists the names of Messrs. F. Sander & Co., St. Albans, and Blair, gardener to the Duke of Sutherland, are announced as exhibitors. The examination of foreign consignments, which under the existing law as to phylloxera would have to undergo inspection en route, will be conducted within the Exhibition buildings. During the time that the Exhibition is being held there will be discussions by the German Rose Growers' Union, the German Garden Trades' Union, and others. Particulars can be obtained from the office of the Society for the Advancement of Horticulture, Invalidenstrasse, 42, Berlin.

— **HORTICULTURAL CLUB.**—The annual dinner took place on Tuesday, Feb. 11th, at the Club Rooms (Hotel Windsor), when there was a very full attendance. The chair was taken by the Chairman of the Club, Mr. John Lee, and there were present—Sir John T. D. Llewelyn, Bart., Dr. Hogg, the Rev. W. Wilks, the Rev. F. H. Gall, Messrs. T. B. Hayward, P. Crowley, Harry J. Veitch, J. H. Veitch, George Paul, George Deal, T. W. Girdlestone, H. J. Pearson, W. Bull, J. Stewart Dismoor, George Bunyard, A. Turner, Lynton White, W. Baker, J. C. Cousens, C. T. Druery, Arnold Moss, the Secretary, &c. In the course of the evening a selection of vocal and instrumental music of a very high order of excellence was given, under the kind arrangement of Mr. Geo. Bunyard, and altogether the banquet was a very successful one, and many good wishes were expressed for the prosperity of the Club.

— **THE WEATHER IN THE METROPOLITAN DISTRICT** has been variable. The concluding days of last week were wet and foggy, but Sunday, Monday, and Tuesday have been bright, the wind varying from S.W. to N.E., with morning frosts on several occasions. The buds of trees and outdoor plants are advancing fast under the influence of the sunny days.

— **THE WEATHER IN THE NORTH.**—February 10th to 17th. The first half of the week was bright but cold, with east wind, and frost from 2° to 8°. About a quarter of an inch of snow fell in the afternoon and evening of the 13th, and the hills around are still white, a cold thaw prevailing lower down.—B. D.

— **GISHURSTINE.**—We are requested to state that this preparation, which is advertised, is largely used by sportsmen on their shooting and fishing boots, is now being applied to walking boots and shoes. It has been found that applied even to the soles of ladies' boots it prevents damp reaching the feet.

— **GARDENING APPOINTMENT.**—Mr. William Hockey, foreman at Cardiff Castle Gardens, has succeeded Mr. Armytage as gardener to Col. Page, Dulwich House, Llandaff.

— **TRADE ANNOUNCEMENT.**—Mr. Sidney Ford, lately of the Leonardslee Gardens, Horsham, has commenced business as a consulting landscape gardener at The Laurels, Cowfold, Horsham.

— **PROPOSED HALL FOR HORTICULTURE.**—Through the accidental misplacement of two small words in our reference to this project last week, the sentence read that Miss Douglas and others promised £25. It should have been, Messrs. Douglas and the other gentlemen mentioned, and Miss Sullivan.

— **WARE AND DISTRICT HORTICULTURAL MUTUAL IMPROVEMENT SOCIETY.**—This Society met twice during January. The members are steadily on the increase. On the 28th January Mr. H. Brown read a paper on *Odontoglossums*, which was much appreciated. On the 11th of February a paper on "The Cultivation of Soils for Garden Crops," dealt with in an able manner by Mr. W. M. Alexander. A good discussion followed. The paper could not fail to be instructive.

— **HYBRID AZALEAS.**—Many will remember that when Mr. Carmichael was at Sandringham he succeeded in raising and flowering a number of hybrids between *Azalea amœna* and, I think, *A. phœnicea*. I remember very well seeing them there in flower, and on visiting High-bury, near Birmingham, a few days since, I saw several of the Carmichael varieties in flower. One of them, especially Mrs. Gerard Leigh (I think this is one of the Sandringham varieties) is very beautiful, of a bright ruby red colour, larger in flower than *amœna*, but of compact dwarf habit and a very profuse flowerer. Truly it is a gem for early work.—D. S. H.

— **THE PARSLEY-LEAVED BRAMBLE.**—In response to your editorial footnote appended to my remarks upon the origin of the above, page 118, I communicated with Messrs. Fisher, Son & Sibray upon the subject, and the enclosed is their reply, just received, in which they give what information they can upon the subject.—W. K. W. "You are quite correct as to the origin of this variety, but we cannot give the exact date of its discovery, but in looking through our former catalogue we find it quoted for the first time in the list for 1859-60, and we are of opinion that this is about the date of its introduction.—FISHER, SON & SIBRAY."

— **AN influential committee** has been formed, says *Nature*, for the purpose of securing the scientific and other friends of the LATE DR. McNAB, PROFESSOR OF BOTANY IN THE ROYAL COLLEGE OF SCIENCE, DUBLIN, an opportunity of expressing their appreciation of his work and their respect for his memory. "Through no fault of his own, Prof. McNab was unable to make adequate provision for his wife and five children; and it is proposed that the memorial shall consist of a fund, sufficiently large to be of real service to his family. Many subscriptions have already been received or promised. Mr. Greenwood Pim, Easton Lodge, Monkstown, Co. Dublin, acts as Hon. Secretary; Prof. W. N. Hartley, F.R.S., Royal College of Science, Dublin, as Hon. Treasurer. As Professor Hartley has been obliged to leave Dublin for some time, all communications should be addressed and cheques made payable to the Hon. Secretary."

— **GARDENERS' IMPROVEMENT SOCIETIES.**—These, which may be termed local schools of gardening, appear highly popular. The Ealing Society had a crowded meeting last week, at which G. Deal, Esq., presided, a paper was read, discussion conducted, and plants exhibited. A method of encouraging cultivation adopted by the Society in according marks of merit on an equitable basis will, perhaps, be further referred to. A very large meeting of a similar nature was held at Reading on Monday night, this week. New members were enrolled, and good financial support offered by Mr. Sutton, Mr. Palmer, and others towards the library and the Wildsmith Orphan fund. A Gardeners' and Amateurs' Mutual Improvement Society was inaugurated at Croydon on Tuesday evening, at which Mr. J. Wright delivered by request the opening lecture on "Mutual Improvement Societies and their Objects." Rev. W. Wilks, M.A., presided, and much earnestness was manifested in the proceedings throughout.

— **AFTER** reading Mr. Arnott's note and that by "W. T., *Blantyre*," on the WEATHER AND SNOWDROPS, I thought perhaps it may interest them and Mr. Skerry to know that here we had some hundreds of Snowdrops in flower on 4th January, and our young lady sent some on that day to England, and was told by return they had none yet. Our

earliest grew in an open spot on the lawn, where, till November, 1888, they grew under a large Thorn tree, when it was destroyed by a gale of wind. There are about one hundred clumps in this spot, which is raised a little above the level of the lawn, and this would have a good roasting in May and June last year, and may account for their early flowering, assisted by this mild winter. As Blantyre and Rutherglen are so near, I am surprised at "W. T." only seeing one on the 8th. We are not sheltered, being on a wooded brae. Snowdrops in January are quite common, but not so early in the month.—W. E., *Rutherglen*.

— THE LATE MR. G. W. YOUNG.—I was much surprised and sorry to read in the last issue of the Journal of the death of Mr. Young. I have no doubt many more besides myself have benefited by his sound and practical teaching. I always found him ready to give advice, and I can safely say on several occasions I have received useful hints from him, which I had no fear about carrying into practice, especially in plant culture. I need scarcely say that my sympathy rests with his widow and family in their bereavement.—J. PETHERS.

— HOMALOMENA (*CARMERIA*) WALLISI is not grown so generally as it should be. It is a handsome plant, belonging to the Aroidæ, of low growing habit, not more than 9 inches high, with drooping leaves, 6 to 8 inches long by 5 inches wide, ovate oblong, and pale velvety green, copiously blotched with golden yellow. The under surface is dull red. The flowers are rather attractive, the spathe being about 3 inches long, constricted in the middle and reddish brown, while the spadix is red. To ensure good leaves, however, the flowers should be picked as soon as seen. We grow this plant in the warmest house, potted in a mixture of peat and moss, and keep it very wet. Under this treatment it gives great satisfaction. It should be propagated by division.—(*The American Garden*.)

— THE SCHEDULE OF THE ROYAL AQUARIUM EXHIBITIONS FOR 1890 is just to hand, and gives particulars of the following:—Spring Shows on March 12th and 13th and April 29th and 30th, when prizes are offered in twenty-one and thirty-one classes respectively, chiefly for bulbs, forced plants, Auriculas, Primroses, and Narcissus. The Summer Show takes place on May 21st and 22nd, when there will be liberal provision in twenty-six classes for flowering and foliage plants and cut flowers. The Rose Show is fixed for June 27th and June 28th, and the National Pink Society offers prizes in ten classes for the same date. A Carnation Show will be held on July 29th and 30th. A fruit Show is announced for October 15th, 16th, and 17th, when the National Chrysanthemum Society offers prizes for Chrysanthemums. The early autumn Show of the same Society takes place on September 10th and 11th, and the Centenary Festival on November 13th and 14th. Meetings of the British Fruit Growers' Association are announced for June 27th and October 15th.

— CINERARIAS FOR HOUSE DECORATION.—When well grown, the varied beauty and bright colours of the Cineraria will always insure for it a high position in general favour. In the greenhouse it is indispensable, while as a plant for the house it is also valuable. As I keep from thirty to forty plants indoors, I have had every opportunity of proving its merits, and I am much in favour of the blue varieties. Other colours I tried, but not with such good results. The blue varieties I am in favour of are the tipped ones. Some have stood a month indoors, but before being taken in, the soil is covered with moss, which is kept wet, and I find it helps to maintain their freshness. I find the colours most brilliant of the plants which were supplied with farmyard liquid manure. The doubles I intend to try next season, but I have not so much confidence in them as in the singles. Perhaps some other readers will give their experience.—R. V. S.

— GAS-HEATING HOUSES.—In reply to "C. S.," respecting an automatic arrangement for regulating the supply of gas used in heating small greenhouses, I can recommend a very ingenious, yet simple, and undoubtedly effective contrivance, that is extensively used in this neighbourhood. The principle of its action consists in the expansion or contraction of spirit enclosed in a thermostat by a column of mercury, the gas being conducted by an inner tube subject to the passage being contracted or enlarged by the heat of the house, causing the column of mercury to rise or fall. This is merely an outline of its action, but several important improvements have been recently effected by one of our most practical heating engineers in the city, and the instrument, which can now be seen in use in several amateur conservatories in Clifton, can be adjusted in such a manner that any desired temperature can be assured. I shall be pleased to forward address of maker if "C. S." will favour me with his address through the Editor.—M. COOMBE.

— PRESTON AND FULWOOD HORTICULTURAL SOCIETY.—An interesting meeting of this Society was held on Saturday last, when Mr. Alfred Waters, of Farington House Gardens, was presented with a handsome clock. Mr. Waters is leaving to take charge at Hopwood Hall Gardens, near Manchester, and the members decided to take this opportunity of recognising his many good qualities and his usefulness to the Society. Mr. C. Parker made the presentation, and in doing so he alluded to Mr. Waters' skill as a gardener and as a successful exhibitor, and also to his willingness at all times to give to others the benefit of his experience on any gardening matter, and that, though the members were all sorry to lose him as a friend and adviser, they wished him every success. Mr. Roberts and others also bore testimony to the respect in which he was held. Mr. Waters feelingly replied, thanking the subscribers for their kindness, &c.

— The *Botanical Gazette* published at Crawfordsville, Indiana, gives some particulars of one of the most magnificent bequests ever made for scientific purposes, that of the late Mr. H. Shaw for the endowment of the BOTANIC GARDEN AND SCHOOL OF BOTANY AT ST. LOUIS, MISSOURI, amounting to not less than between three and five million dollars. The trustees have determined to apply the income to the maintenance and increase in the scientific usefulness of the Botanic Garden; to provide fire-proof quarters for the invaluable herbarium of the late Dr. George Engelmann, and to supply means for its enlargement; to secure a botanical museum; and to gradually acquire and utilise facilities for research in vegetable physiology and histology, the diseases and injuries of plants, and other branches of botany and horticulture. To aid in the carrying out of this last purpose travelling botanical scholarships have been established. The present very able director of the Botanic Garden is Dr. William Trelease.—(*Nature*.)

— A "MARYLAND FARMER" writes in *The Canadian Horticulturist*—"The extensive use now made of PARIS GREEN and other arsenical poisons should be a warning to us. Some of our ablest physicians insist that there are forms of disease traceable directly to the presence of arsenic in the Potato. This I doubt, and yet it seems certain that the use of arsenic on vegetation more or less checking the perfectly healthy development of the leaves, produces a chemical change in the tubers detrimental to health. It is getting almost impossible to purchase Potatoes entirely free from a tinge of bitterness, while a very large part of the Potatoes that find their way to market are quite unfit for use. Many farmers use five or ten times as much Paris green on a Potato field as is necessary for the purpose of destroying the Colorado beetle. The practice of sprinkling Paris green into Cabbage heads is criminal and inexcusable. I have recently seen the account of five persons having been killed by the use of such Cabbage. Probably there is no direct danger from the recently derived method of spraying Apple and Plum trees to the fruit eater, but there is serious danger to those who handle the poisons. Paris green should be used and stored with every precaution. We are getting quite too familiar with it, and are losing our fear of it."

— THE NATIVE GUANO COMPANY send us a list of testimonials, showing the results of the application of the manure to farm and garden crops in the different counties of England, also in Wales and Scotland, and it has evidently given great satisfaction to the several cultivators.

— A VALUABLE paper on "THE UTILITY OF FORESTS AND THE STUDY OF FORESTRY" was recently read before the Indian section of the Society of Arts, by Dr. W. Schlich, Professor of Forestry at the Royal College of Engineering, Cooper's Hill. In the course of his remarks Dr. Schlich gave an account of the instruction in forestry at Cooper's Hill, and mentioned that the authorities were thinking of appointing a second professor of the subject, and thus doubling the amount of instruction now given. After the reading of the paper Major-General Michael, C.S.I., who presided, made some interesting observations. No one, he said, who had visited the great forest regions of Germany, Austria, and France could fail to be impressed with the visible effects of good management, and to wish they were more generally apparent in England and Scotland. There were signs that the education and practical training of foresters were being more thought of at the present time in England, and he ventured to predict that Dr. Schlich would shortly have a good many students under him who were destined for home employment and not for India only. Personally he knew more about the value of forestry and the life of a forester in India, having spent seven or eight of the happiest and perhaps the most useful years of his youth as a forest officer. That was

more than forty years ago, before the time arrived for experts like Dr. Schlich and his distinguished predecessor Sir Dietrich Brandis to come to the country. He could, therefore, tell any of Dr. Schlich's students that might be present that the life of a forester in India was not only a career of importance, but that it was one full of interest and of real enjoyment.—(Nature).

PERPETUAL FLOWERING CARNATIONS.

JUDGING by the rarity of well-grown examples of perpetual-flowering Carnations it is easy to believe that the culture is not generally well understood, while border varieties are much more largely grown. The time is now fast approaching when the propagation should receive attention from those who wish to have first-class plants for next autumn's flowering; a few words of advice therefore are here given. It is generally well known that to build up healthy vigorous specimens of any plant an early start must be made with robust healthy cuttings, and the truth of this is as applicable to the Carnation as to any plant I know; those therefore who require fine plants in 8-inch pots should see to it at once. By an early start I mean that cuttings should be inserted from the middle to the end of February, others following in quick succession. To obtain cuttings of the right stamp it will be necessary to turn attention to the stock plants without delay, as should these be in a temperature of 45° to 50° it will be beneficial to give a rise to 55°, with an additional rise by sun heat. The object of this increased temperature is to produce what may be termed "growing cuttings"—that is, cuttings which have been comparatively quiet for some weeks past, and which will quickly answer to a rise in the temperature. These active or "growing cuttings" are much surer in the rooting process when produced as above named than would be the case were they detached and inserted in their semi-dormant state, while if produced in too high a temperature they are more liable to damp while still in the cutting frame. To prevent damping in the early Carnation cuttings daily attention is essential, with judicious applications of water at all times, admitting air according to circumstances, and whether bright or dull, but on no account close the frame directly after watering. In taking the cuttings I always prefer those I have attempted to describe—viz., "growing cuttings;" these may be 5 or 6 inches in length, and preference always given to those which can be had with a heel attached, as these are, so far as my experience goes, less liable to damp in the early stages.

A suitable compost for the cuttings will be found in equal parts of good loam and well decayed leaf soil, with a liberal addition of sharp sand. The pots should be drained to one-third their depth and the drainage cocoanut fibre refuse; afterwards fill up with the soil to within three-quarters of an inch of the top of the pots, press somewhat firmly, and add half an inch of clean washed silver sand on the surface. I prefer the latter quite dry, so that it may, when the cuttings are inserted, run down beside them.

Many prefer thoroughly watering the soil prior to inserting the cuttings, by which means the sand is confined to the surface, and in my opinion debarred from performing the functions intended, especially as Carnation cuttings are inserted 1½ inch deep. Another important item is the propagating frame and the amount of bottom heat necessary. In respect to the former any kind of frame that can be kept close will suit, while a uniform bottom heat of 65° will suffice for their requirements. Plunge the pots in cocoa-fibre refuse, and then give a thorough watering, leave them uncovered till the cuttings have become dry, and then place the lights on and keep them closed. Cuttings thus treated should not in the temperature cited require any more water for a week at least at this season of the year; the cuttings, however, may be examined daily in the morning, and if the foliage is wet remove the lights for an hour. When another watering is necessary it is a good plan to give it in the evening and leave the cuttings uncovered during the night, though later in the season such a step would not be altogether prudent, as flagging may ensue.

Overcrowding the cuttings both in the pots and when plunging them must always be avoided, for nothing is more conducive to damping. Where but limited quantities are required it is a good plan to insert cuttings singly in small thimble pots, from which they may be shifted into larger sizes. In a month or so the majority will be rooted, and not a day should be lost in placing them singly into 3-inch pots, using good loam and leaf soil in equal parts, to which add of well decayed manure about one-sixth, and a like quantity of sharp sand or grit, always potting firmly, and give a thorough watering when the operation is completed. By the time the young plants have taken to the soil they will need stopping, that is pinching with finger and thumb the top of the plant, but not removing more than to the first joint; this will cause the plant to break from below, and when the breaks are an inch or so long the plants may be shifted in large 48's or 5-inch pots, using soil of the same kind and in similar proportions cut somewhat rougher than before. From the time the young plants are first potted a temperature of from 50° to 55° will suit them, and during these early stages keep green fly and the like at bay. In these latter sized pots they will be safe till the first or second week in June, when they should be ready for 8-inch pots and for standing outside on a bed of coal ashes, having been previously staked. Attention to small details in the earlier stages is the forerunner of success, this, coupled with day to day watching and careful watering, till the roots have taken to the final shift will invariably result in healthy plants and plenty of early blooms. To

often these plants are propagated much too late in the season, with the result that they are making growth when the buds should be forming, and Carnations that have not set their buds, or are in process of setting, by the end of September will be of little use for producing many flowers during the ensuing winter, and to late propagation may be traced much of the disappointment arising out of these plants failing to flower during the winter months.—J. H. E.

CALIFORNIAN FRUIT.

I HAVE read with interest the articles that have appeared recently in your valuable journal on emigration of gardeners. The enclosed, written on the spot, may be of interest to your numerous readers. It is taken from the *San Francisco Examiner* of December 29th, 1889, and certainly is most encouraging to those seeking knowledge on emigration to those parts, and I trust it may catch the eye of him who sailed January 4th in the "Wyoming" for America.—ALFRED OUTRAM, *Victoria and Paradise Nurseries, Upper Holloway, London, N.*

IT is a matter of great astonishment to all strangers arriving in California that there exists here in the vicinity of a flourishing city an utter destitution of all garden culture, and especially of those culinary vegetables so necessary to the comfort and health of its inhabitants. At this time there is not in the vicinity of the city one acre of cultivated ground devoted to this object, while on the other hand the few vegetables brought to our markets command such exorbitant prices that a much larger portion of gold might be obtained from the earth by the culture of esculent vegetables than the average obtained by digging for gold at the mines; in fact, it may be deemed an absolute certainty that some scores of the persons now idle or engaged in branches of business that have become overdone and stagnant might realise ample fortunes by the healthy occupation of horticulture, a business which affords immediate return to those who engage in it. We might also refer to fruits and to the total deficiency of orchards in our vicinity from which this city might be amply supplied in lieu of the present dependency for the paltry quantities we receive from the distant missions. A few bushels of indifferent Pears and Apples, bruised by the transportation from distant towns, are all that our markets have been favoured with, for not a tree of even these commonest fruits is to be found adjacent to our city. As to Peaches, Plums, Cherries, Grapes, and other fine fruits, we should absolutely forget that any such existed were it not that some of these are to be met with in a dry state. All these varieties of fruits could be successfully cultivated here, and would serve greatly to increase the comforts of a California home. The smaller fruits—such as the Strawberry, Raspberry, Blackberry, and Currant—are found growing naturally in different sections of the country, thus affording proof of the appropriateness of the climate to the growth of the finer varieties so generally cultivated in the Atlantic States and Europe. We have hitherto been pressing onward in the erection of stores and dwellings for all branches of mercantile business, in order that there might be ample room for the multitude arriving and for the storage of all merchandise. These points seem now to have been attained, or at least sufficiently so for the present, and we may now consequently spare the time for some attention to the gratifications and comforts of life.—(The *San Francisco Examiner*.)

MR. LEONARD COATES, Napa Valley Nurseries, writes:—"During 1888 were exported from California 65,000 tons of fruits, divided as follows:—27,000 tons green fruits, 20,000 tons canned fruits, 10,000 tons dried fruits, 8000 tons raisins, representing an equivalent to 137,000 tons of green fruits. This does not include the very large items of Oranges and Lemons, consisting of thousands of tons, or of Almonds, Walnuts, &c.; nor does it include the enormous consumption in California. Add to this 20,000,000 gallons of wine, the total of 1888 vintage, where Australia's output is, I believe, about 3,000,000 gallons, and it is a fairly good showing for a desert."

PRESERVING VEGETABLES.

FOR some years Messrs. Carter & Co., High Holborn, have adopted a method of preserving vegetables for exhibition purposes which has proved very satisfactory. It has been gradually improved and patented, and they are now enabled to produce excellent samples of all the chief vegetables. A display of these in the office window at Holborn evidently proves extremely attractive, for on several occasions we have seen quite a crowd of spectators, who are evidently puzzled by the appearance of fresh-looking Peas in midwinter. For seed shops such specimens are especially well adapted, and it is for this purpose they are recommended. One great advantage they possess over models and ordinary artificial preparations is that they faithfully represent every peculiarity of form distinguishing the variety, and they are thus in a sense of educational value from a gardening point of view.

The method being a patent one of course Messrs. Carter do not explain the whole of the process, but the principle is that after the vegetables have been prepared they are coated with a thin wax-like substance, which resists the action of heat however, and this hermetically seals the specimen, protecting it from the air, and consequently ensuring its preservation for an indefinite period. The substance is then coloured in exact imitation of the vegetable enclosed, and a further coat of a transparent varnish prevents the colour fading by exposure.

Peas, Beans, Beet, Radishes, Carrots, and Tomatoes are remarkably well represented, and in the Holborn display there are twenty-five sorts of Peas, two Beet, three Radishes, fourteen Beans, five Carrots, and nine Tomatoes. The last-named make very effective samples prepared in the manner indicated.

TABLE PLANTS.

THE demand for graceful plants of moderate size and with brightly coloured or clearly variegated foliage is rapidly increasing, and every addition is readily welcomed that will impart some variety to those already in use. We have published several illustrations of plants adapted for this purpose, and another is now given (fig. 24) representing an excellent and elegant plant. It has a somewhat cumbersome name—*Anthericum albo-medio pictum*—that is not likely to increase its popularity, but the merits of the plant are sufficiently pronounced to ensure it a large share of attention. The leaves are tapering, narrow,

Sarracenia Chelsoni, *melanorhoda*, *Wrigleyana*, and *porphyro-neura* Ferns.—*Pteris serrulata*, *cretica nobilis*, *hastata*, and *adiantifolia*; *Adiantum farleyense*, *euneatum*, *cardiochlena*, *fulvum*, *setulosum*, and *macrophyllum*; *Nephrolepis Duffi*, *Doryopteris palmata*, *Polypodium aureum*, *Scelopendrium vulgare* and *Kelwayi*.

A SIEVE FUMIGATOR.

FUMIGATING is a necessity in all gardens, great or small, where such plants as Roses, Pelargoniums, and *Caleolarias* are grown. Peach trees need it either for green or black fly, and so do Vines occasionally, and as the time is fast approaching when fly of both colours will be on the increase, I thought a note on the subject might be useful to some who do not understand the best method of performing what is to some a very disagreeable task. Many men—myself among the number cannot stand the smoke without feeling giddy during the time it is necessary to remain in the house. We use a large sized sieve, having an inch

FIG. 24.—ANTHERICUM ALBO-MEDIO PICTUM.

and gracefully arching; white in the centre, and edged with green. It seems to keep its variegation well and requires but little heat.

This *Anthericum* and the following useful table plants were shown by Messrs. J. Veitch & Sons at the Royal Horticultural Society's meeting on October 22nd, 1889. Those with variegated foliage are marked with an asterisk. *Dracaenas angustata*, *angustifolia*, *Cooperi*, *terminalis*, *norwoodiensis*, *Louisa*, *terminalis alba*, *Doucetti*, *Ernesti Frederiei*, and *gracilis*; *Crotons elegantissimus*, *Countess*, *Johannis*, *angustifolius*, *Chelsoni*, and *volutus*; *Aralias Veitchei gracillima*, *Kerchoveana*, *Chabrieri*, and *elegantissima*, *leptophylla* and **monstrosa*; *Panax Victoriae* and *fruticosum multifida*; *Carex viridis* and **variegata*, **Bambusa Fortunci variegata*, **Pandanus Veitchei*, **Ananassa sativa variegata*, *Asparagus plumosus nanus* and *tenuissimus*, *Tillandsia Zahnii*, **zebrina*, **majus*, and **tessellata*, *Nidularium amazonicum*, *Nepenthes Mastersiana*, **Fittonias Pearcei* and **argyroneura*, **Ophiopogon spicatus*, **Acalypha musaicus*, **Begonias Arthur Malet* and **Louis Chrétien* (improved), **Gynerium argenteum variegatum*, **Eurya latifolia variegata*, *Anthericum latifolium*, and **albo-medio pictum*, *Cocos Weddelliana*, *Geonoma gracilis*, *Kentia gracilis*, *Thrinax elegans*, *Kentia Belmoreana*, *Areca Verschaffelti*, *Phoenix rupicola*, *Solanum Capsicastrum*, **Ficus Parcelli*, *Grevillea robusta*, **Aspidistra lurida variegata*,

mesh, turning it upside down on the floor of the house. If placed on three bricks laid in triangular form so much the better, as more draught would be obtained, although there is a difficulty in seeing the bricks when the house is nearly full of smoke, and the position of the fumigator requires changing, as it does constantly, to distribute the smoke evenly. On the wire of the sieve we place three or four red hot cinders about the size of a hen's egg. These are covered with tobacco paper, which has previously been torn to pieces about 3 inches square. If at all dry—as it should not be—the paper must be wetted, using a fine-rose waterpot. Attention is necessary to prevent the paper blazing and burning too rapidly. Keep the waterpot always at hand ready for this. Some people cover the paper with damp moss; I do not care for the plan, as it prevents the tobacco paper burning so freely as it would do without the moss.

The advantage of using a large sieve is that a greater surface is given from which more smoke is obtained. The greater the amount of smoke at once the quicker is the house filled, and that being the object, the most ready method should be sought. If the cinders are spread all over the sieve a greater body of smoke will be obtained than is possible from any other kind of fumigator that I have seen. When the house which has to be fumigated is a large one, two sieves might be used with advantage at the same time. For the last eight years we have used no other kind of fumigator than a coarse-mesh sieve, and I consider a cheaper or a more efficacious one cannot be found. If the tobacco paper is in a right state, well pulled to pieces of the size named, very little attention is

needed. If there is any doubt in the mind of the operator that the aphides are not killed by the one application, it is better to fill the house with smoke in the morning succeeding the evening on which it was done first. Afterwards a vigorous syringing should be given, which would rid the plants of both fly and dust alike. Tobacco smoke is, perhaps, the best destroyer of black aphides upon the young shoots of Peach trees. Certainly it entails the least labour in applying it, rather than dipping the affected parts in liquid of some sort; generally two doses of smoke will remove the fly altogether. It is better to prevent green or black aphides attacking the tender shoots of Peach trees by a timely fumigating of the trees before the buds burst into bloom. If this be done such trees are seldom troubled with fly. In the case of Pelargoniums or Calceolarias, plants most subject to attacks of aphides, never wait until you see two, but smoke the plants upon the appearance of the first.—H.

BOUVARDIAS.

MR. BARDNEY has given us some excellent instructions on growing Bouvardias. He does not, however, say much in favour of the planting out system. Perhaps he is too far north. Here, in the south-west, they do well planted out during the summer months, but I have known failures to occur from various causes—viz., in the cold wet season of 1888 my plants were very unsatisfactory. A few years ago I saw some at a neighbouring place which were planted in an unsuitable position. This year a friend of mine has failed with them, owing to their being planted too thickly together, so they could not be properly lifted. The first cause of failure none of us can avoid, but the two others we may. We have generally been successful with Bouvardias, and this year particularly so.

Our plan is to make a trench a foot in width, throwing out 4 or 5 inches of soil, that remaining in the trench being well broken up a good spit in depth. The soil which was taken out is replaced by a similar quantity of well decayed material from the refuse yard, passed through a half-inch screen, to which is added a good portion of road grit or other sand. This is well mixed with the upper 4 inches of the natural soil in the trench, and made fairly firm by treading. The Bouvardias are then planted in the centre of the prepared trench, the distance apart being regulated according to the size of the plants. Those which are now occupying 10-inch pots, 20 to 24 inches apart would not be too much. Watering and syringing in dry hot weather is attended to, which, with the necessary stopping, is about all they require.

About a fortnight before potting time arrives the plants are lifted by means of two steel forks inserted opposite to each other at 8 or 9 inches from the stems; the ball is then let carefully into its hole again, and well trodden down. A good soaking of water is given, and if the weather is not showery the plants are frequently syringed for a few days. If they flag a little no fear need be entertained; still it is not desirable. When taken up for potting they are lifted in the same manner as before, care being taken each time not to break the balls. Some of the outside soil is gently rubbed off, in order to get them into pots of proportionate size. Rich soil is used for the bottom and for finishing off the surface, but no attempt is made to ram any down the side of the ball, as the smallest sized pot is used into which it is possible to get the ball of roots. A close pit is in readiness to receive the plants as soon as they are potted. Watering, syringing, shading, and gradually inuring them to the air, comprises the treatment required until they are established, when they may be arranged where they are to flower. Our best flowers are all out, or I should have sent a few for your inspection. I cannot agree with Mr. Bardney that "they are seriously checked however carefully lifted."—T. S., *Henbury Hill*.

THE NATIONAL CHRYSANTHEMUM SOCIETY: THE CENTENARY FESTIVAL.

A MEETING of the General Committee of the above Society was held in Anderton's Hotel, Fleet Street, on Monday, February 17th, at 7 P.M., when there was a large attendance of members, E. C. Jukes, Esq., presiding. After the minutes of the last meeting had been read and signed, and some miscellaneous business had been transacted, including the admission of the Norfolk and Norwich Society into affiliation with the National, the election of five members of the Floral Committee to fill the vacancies caused by the retirement of that number (one-third of the total) in accordance with rule 9. The retiring members were Messrs. Addison, Cannell, Boyce, Gordon, and Gibson, who were re-elected with the exception of the first-named, Mr. Jones of Lewisham being added; seven were proposed. The dates of the Floral Committee meetings were fixed for September 10th, October 15th, October 29th, November 11th, November 25th, December 10th, and January 7th. The Floral Committee regulations were discussed at some length, more particularly with regard to rule 5, which is as follows:—

"5.—In the event of any variety being staged by more than one exhibitor at the same meeting the whole of the exhibits of that variety

shall be submitted simultaneously, and the awards made (if any) shall be made to the exhibit or exhibits staged in the best condition."

This rule had some bearing upon a legal action last year with regard to the certificating of a certain variety, and some thought that a certificate should be awarded to every exhibit which represented the variety in good condition. Sometimes the difference in quality between one which secures the certificate and others that do not is very slight. However, it was ultimately resolved that no alteration should be made, and the rules were adopted, as also were the Exhibition regulations.

The principal business of the evening was the presentation of the report by the Centenary Festival Sub-Committee. It was read by Mr. W. Holmes, and the substance was as follows: It was recommended that the Festival should be held on November 11th, 12th, 13th, and 14th in the Royal Aquarium, Westminster, that the first two days be devoted, as usual, to a Chrysanthemum competition, and the remaining days to a grand general display and fête. The preliminary programme is that Tuesday, November 11th, be devoted to the competition and exhibition with an opening ceremony, the arrangements being under the superintendence of Mr. R. Ballantine, Mr. W. Holmes, and Mr. G. Drain. Upon Wednesday, November 12th, conferences and other attractions will be provided under the management of Mr. Lewis Castle, Mr. G. Gordon, and Mr. C. H. Payne. On Thursday, November 13th, a banquet will take place under the management of Mr. T. Bevan, Mr. R. Dean, Mr. H. Briscoe Ironside, and Mr. John Laing. Friday, November 14th, will be devoted to Conferences, &c. It was further recommended that special centenary medals be presented to the affiliated societies to be included in their respective schedules, and that in some of the leading classes in the National schedule similar medals should also be presented to all the competitors, whether prizewinners or not.

The schedule, the production of which had been included in the sub-committee's work, next came under consideration. The completed list of Judges comprise the following:—

Plants.—Messrs. D. Donald and G. Prickett.

Cut Blooms.—Messrs. R. Dean, George Gordon, J. Kendall, H. Turner, Lewis Castle, and W. G. Head.

Fruit and Vegetables.—Messrs. G. T. Miles and G. Wythes.

Miscellaneous Exhibits.—Messrs. H. Herbst and E. C. Jukes.

The leading addition to the schedule was a centenary class for forty-eight cut blooms, twenty-four incurved and twenty-four Japanese, distinct varieties. The prizes were £25, £20, £15, £10, and £5, with a bronze centenary medal for each exhibitor. Special classes were provided for the four Veitch medals and prizes of £5, to which the Society added second and third prizes. A class was inserted for eighteen incurved blooms, excluding the Queen family, in which the proprietor of the *Journal of Horticulture* offers the first prize of £5. Special prizes are offered by Messrs. John Laing & Sons and a number of other firms. The value of the prizes have been increased in some cases, and altogether the Society is offering a much larger amount than at any previous show.

Proof copies of the schedule were distributed amongst the members, discussion was invited, and a few suggestions were made. It was decided to extend the space for floral decorations, a silver-gilt and a silver medal being offered in addition to money prizes. The report and schedule were then unanimously adopted, and the meeting concluded with the usual vote of thanks to the Chairman.

LARGE CHRYSANTHEMUM BLOOMS.

IT has become a debatable question whether in encouraging the production of such abnormally large Chrysanthemum blooms as are now considered, by those who are termed experts, worthy of prizes, this useful and now very fashionable flower is not being spoiled. There are various sides to this, as there are to every other question. Whether Chrysanthemums are being spoilt by being grown on what I shall term the tall, and two-or-three-blooms-to-a-plant system, for the sake of producing flowers of the greatest possible size and perfect symmetry, it is quite certain that if competitors are to find their names among prize-winners, according to the present standard or ideal, they must adopt it. This fact does not, of course, prove that societies are encouraging good taste, or a profitable way of spending labour and means in offering prizes for blooms of such extreme size produced in twos and threes from one pot, and from unsightly plants ranging from 6 to 10 feet high.

A celebrated nurseryman, who has the most ample means of knowing what is going on in the gardening world, said at the Edinburgh Show that it was his opinion that the rage for monster blooms was doing much harm in directing the labour power of many gardens into a wrong channel, and one that served no good end, classing it in this respect with the carpet bedding system, where thousands of plants had to be reared for the sake of having a toy bed or two that produced no general effect worthy of any garden, and led to an immense waste of labour. In looking at the subject from the standpoint of a large family supply of cut blooms and decorative plants I endorse this opinion, and this fishing-rod system of cultivating this lovely flower is one I would not adopt. It may be questioned very much if it is doing any good for the Chrysanthemum as a flower, or for gardeners and gardening. I was induced to try it for once, but was, shall I say, so disgusted with amount of labour entailed in the production of a few blooms, and with the unsightliness and inconvenience of such tall and gawky looking plants that, unless by a direct order, I would never do it again.

Let it be for a moment considered what labour and expenditure of

materials is considered necessary by an expert to enable him to place forty-eight distinct prizetakers on the board. He must grow 300 plants, 150 in each section, in 9 and 10-inch pots, thus making it necessary to have more than three pots for the production of every bloom that will be serviceable to him on show days, and surely the question may be asked if the "game is worth the candle." Apart altogether from showing, and taking the whole blooms produced thus, it would be difficult to invent a more expensive system of culture, requiring, as it does, a very great amount of labour and the most constant and watchful care. I am not altogether a despoiser of moderately large blooms in moderate numbers, because for certain purposes in connection with home decoration they are very useful, effective, and much appreciated. It may safely be asked if greater numbers of blooms of lesser sizes, and produced from a third or a sixth the number of pots, leave anything to be desired on the score of size, if indeed they be not more desirable than the monster blooms. That three or four times the number of blooms, ranging from 5 to 8 inches in diameter, can and are produced from the same sized pots is a well known fact, and surely such blooms are large enough for any purpose short of prizewinning according to present standard. For decorations in which numbers of small glasses holding a single bloom are needed, these larger than ordinary flowers are most effective, and they can be produced in from nine to twelve and more in 9 and 10-inch pots with much less labour than one tall one producing three flowers necessitates.

By adopting the cutting-down system—I believe first practised many years since by Mr. John Laing of Stanstead Park Nurseries—a great number of what, in comparison with bush plants, may be termed extra-sized blooms are produced, with a vast deal less labour than is involved in the production of prize blooms. It scarcely needs to be explained that nine or ten stems from 2 to 4 feet high with a single bloom on each in a 9-inch pot, or a greater number in a 10-inch pot, require much less labour than the same number of blooms on tall plants requiring four or five times the number of pots. In the last week of December I cut eighteen blooms of Ralph Brocklebank from a plant in a 10-inch pot, and most of the blooms were 8 inches in diameter, and I think such proportions are ample for any—too ample for most—purposes.

Dwarf plants produced on the cutting-down system have many points to recommend them as compared with their lanky compeers. They can be made available for many purposes as plants for which tall ones are useless, and when stood on the floor of a house can be looked down on, enjoyed, and attended without any inconvenience. For a large family supply the proportion of such plants to bush plants need not be more than a half or a third, simply because far more of a lesser size of blooms are required for family use. Even with the by no means very limited glass houses of this place the tall plants were found a sort of white elephant. They had their blooms up among the wires of a large orchard house, in many cases needing steps for a 6-foot man to attend to the blooms and gather them; whereas on the cutting-down principle the plants ranged on each side of an orchard house path one had to reach down to them, and the character and beauty of the blooms could be comfortably enjoyed, the most dwarf varieties being quite available and handy for bench decoration in show houses.

In adopting this way it is best to strike cuttings in December or January in the usual cool way, putting one, two, or three cuttings in a pit according to the size of plant ultimately required. I think in a general rule the preferable way is to have two or three in a pot, and bloom them in 9 or 10-inch pots. They are grown on as vigorously as possible without being stopped till, here, near the end of May, and to produce a long succession of blooms all are cut down at the same time. When all are required at a given time, say the middle or end of November, the late varieties should be cut down quite fourteen days earlier than the earlier blooming sorts. And when such sorts as Mons. H. Jacotot, W. Holmes, Margot, Lady Selborne, &c., &c., are required to bloom along with the white and yellow Madame Desgranges, they should be cut down about the 12th or 15th of May. But from our cut-down section last season we had such as Fair Maid of Guernsey, Belle Paulc, Eve, Mrs. Heale, Boule d'Or, Ralph Brocklebank, &c., as late as the very end of December. One of the chief points is to grow them with as much vigour as possible till cutting-down time, and so to preserve the leaves to their base, and in cutting down not to cut lower than where there are healthy leaves. Three, four, and five breaks may be preserved from each plant, saving of course the most robust. I am quite certain that those growers whose object is home decoration who have not yet tried this plan with a part of their plants will never give it up if they do.—D. THOMSON, *Drumlanrig*.

THE PROFESSION OF GARDENING.

[Read at the Carliff Gardeners' Improvement Society.]

WHEN we speak of a gardener we at once think of a private garden. We associate gardeners with a garden proper, and in my opinion they are only to be found in private establishments, large or small. True, nurseries, market gardens, places of public resort and recreation, and all the botanical gardens employ skilled men in their various departments, but they are, I think, regarded more as specialists. Market gardeners are confined to vegetables and fruit; florists to flowers. Nurserymen, too, are becoming specialists. We find one celebrated for his Orchids, another for his Roses, others for Dahlias, Rhododendrons,

Coniferae, &c. In our national garden at Kew there is the same tendency to sub-division. In nurseries and in all public gardens we find one set of men detailed with a foreman for this department, and another for that.

In a short paper like this it would be impossible to do justice to the subject were I to attempt to deal with it from all points of view. I propose, therefore, to omit specialists from consideration, and to treat the matter from a private gardener's point of view. Of these there are several grades, commencing with journeymen, foremen, single-handed gardeners, head working gardeners, and head gardeners. Briefly let me first indicate the start of gardeners, and the usual course of training they undergo during their probation. Many of the leading men to-day, could their history be known, started on their successful career as "kitchen lads"—that is, they were engaged by their respective head gardeners to carry the produce of the garden to the house, and to do any light work in the garden. These lads, starting as they do from the lowest rung in the ladder, have the principles and practice of the art more firmly engrafted in them than is the case with those who start as apprentices, and who often expect to go into the houses, and come out finished in two or three years. These lads are gradually trained to the discipline of a gardener's life, and by the time they are permitted to enter the houses they are a long way ahead, and eager for further knowledge. In most cases they pay a premium and become apprentices, and rightly so, for I think the gardener should be compensated for his trouble, otherwise it would be better policy to engage competent journeymen to the exclusion of apprentices. In large places where valuable collections of plants are grown the raw apprentice is an exception. In such gardens they chiefly engage improvers. The difference between an improver and an apprentice is but slight save in knowledge; but it is obvious that any gardener would prefer an improver who is willing to pay a premium, and who has had the benefit of two years' training in a smaller place, to an apprentice who has nothing save his money to recommend him.

For a premium of something like £5 per annum a lad can become an apprentice in a good place, and for a similar sum can enter into an establishment of the highest standing, where the opportunities for improvement are well worthy of the outlay. This is the best course, but in general young men prefer to take a journeyman's situation as soon as they have completed their apprenticeship. They do not remain long as journeymen, as a rule, before they consider themselves fit for foremen. This is a mistake. I would recommend a course of at least four years in this grade, one of which should be spent in a large nursery or at Kew, the remaining three years being divided equally in at least two good private places. Nothing is gained by remaining too long in one place, especially in the case of journeymen.

The next grade, that of foreman, is one of much greater responsibility, and the journeyman who desires to pose as a first-class foreman should be well grounded in practice, as he will have to take the lead. In this position a few years spent in one or two good places should find him fit to take sole charge. Up to this the path is comparatively easy of ascent, but now the case is altered.

Most gardeners starting on their career fix their eyes on a position as chief in some large establishment. This is the goal of their ambition. But, alas! for the vanity of human expectation, how often is it doomed to disappointment? The supply being greater than the demand, it is a question of "the survival of the fittest," as to whom the best places fall; the rest struggle for positions of lesser note, from working head gardeners down to single-handed men. They enter into competition even with those whose ideas of success never soared above a single-handed place, and who have circulated in such places their life through. It is certainly difficult for one who has been accustomed to all the resources of a large establishment to adapt himself so small places, but eventually they get accustomed to their position, their courage returns, and they recommence the ascent. The most resolute and determined have occasionally accomplished the feat of reaching the top in their second endeavour, but the majority resign themselves to inexorable circumstances, and remain single-handed gardeners, or perhaps jobbing gardeners, the rest of their life.

A head gardener in a well-appointed place has a position of great responsibility; but if he has properly fitted himself for the post the duties should sit lightly upon him. He can engage, for the various departments, competent and skilled foremen on whom he can rely; he does no manual labour himself, but he sees that everything is done, and done well. With ample scope and assistance to display his talent in landscape gardening and general improvement, the surroundings of his employer's residence should be a model of good taste and style, and

with every convenience for the production of fruit, vegetables, and flowers his gardens and glass structures should be filled with the best examples of skilful cultivation. Let us now take a glance at the hours of employment and the rate of wages. With regard to the former, a good gardener is nearly always employed, but, generally speaking, continuous labour begins at six in the morning, quitting at five in the evening, with an interval of one hour and a half for meals. In addition to this he has to attend to his houses and fires both at night and on Sundays, while as to wages I think the following a fair average:—

Apprentices and improvers,	10s. to 15s. per week,	with bothy and vegetables.
Journeymen	15s. to 18s. "	" "
Foremen	18s. to 25s. "	" "
Single-handed gardeners	20s. to 25s. "	with residence and vegetables.
Head-working gardeners	25s. to 30s. "	" "

Of the salary of head gardeners I am not able to speak with authority, not having entered the charmed circle, but if we fix their income from £100 to £200 per annum we shall not, I think, be far out, and when we consider other privileges which they are permitted to enjoy we may say that they are fairly well paid. On the other hand, working gardeners have cause, I think, to complain. These men have charge of comparatively large places, often undermanned, regulations to keep as an example to those under them, the worry of striving to keep abreast of others more fortunately placed. The single-handed men are better off than these; their wages are not much less, they have less worry and responsibility, and are in consequence far happier. The bothy referred to in the table of wages is mostly situated within the garden, in which the foremen and those under him reside. It has long been established amongst us, and is, in my opinion, an admirable institution. It creates and fosters a spirit of emulation, and begets a habit of punctuality amongst young gardeners which is of great service to them in after life. And now, having shown the way by which gardens are supplied with men, their time and pay, let us turn and look at the subject from other and wider points of view.

The social position of the gardener is not, I am bound to confess, what it ought to be. We are voted by Society to be a respectable class of working men. The majority of gardeners labour manually. This fact settles the question, and determines our social position. It is useless to speak of the dignity of labour with reference to social position; whatever dignity labour may have in the concrete, it has none in the eyes of society.

If we visit a theatre, and a gardener should be represented on the stage, it is certainly not a very exhilarating spectacle for his prototype in the audience. In literature the case is different. Here we see the gardener appreciated, not ridiculed. Books in abundance on all subjects having relation to horticulture, &c., and most gardeners aspire to the possession of a small library. The number of monthly and weekly magazines and papers are many and good, some of exceptional merit, and when bound form handsome and useful volumes. The ordinary weekly and some of the daily newspapers find it pays to insert a column of matter having reference to the garden. Certainly we are well served by the Press.

Great Britain may be regarded as the headquarters and home of gardening. In no other country in the world is it carried to such perfection. The stately homes which adorn our country are not to be matched elsewhere in the world. The sixteenth and seventeenth centuries saw a great impetus given to landscape gardening. All through our history, up till that period, we do not find gardening much in evidence, but then it commenced its rise from obscurity, and rapidly became recognised as an art. The eighteenth century saw the introduction of exotics, new and rare plants, ornamental trees and shrubs of all kinds. Glass structures became a feature in the gardens of the wealthy, hotanical gardens were established, and literature assisted in the general progress. But remarkable as was the progress made during these three centuries, the nineteenth century is still more remarkable.

The accumulation of wealth in this century has been enormous. It has been estimated that the income of the United Kingdom during the last twenty years has increased six hundred million sterling. Everywhere we see evidence of this great prosperity. In 1760 the Earl of Northumberland (although his household consisted of over 150 persons) kept but one gardener. Compare this with the state of things to-day. Now the gardening department of a large establishment is by far the largest, some of our head gardeners having as many as eighty men under them. During the last twenty years we have seen great improvements and changes. Cheap glass and the cost of erection of glass houses has rendered useless the old heated walls for Peach culture. We

miss the New Holland plants; they are nearly gone, though once a feature; their place is taken by the Orchids. Improvements have been effected in the heating and ventilation of glass houses. Flues are gone, steam was tried and found wanting, and hot water holds the field. By the introduction of the lever system in ventilation a range of houses can be aired to a nicety in a few moments. All these go to make a gardener's life less laborious and more agreeable.

The generation of gardeners that has passed away have left their impress behind them in an unmistakeable manner. Amongst them two men stand head and shoulders above the rest. The noble structure in glass and iron at Sydenham was designed by one who had trod the path of gardening life from his youth, and we are proud to point to Sir Joseph Paxton as one of us; the other, remarkable for his extraordinary perseverance and wide knowledge, won renown as a landscape gardener, and Loudon's Encyclopædias remain a monument to his great capacity and thirst for knowledge. In looking back to the past we are struck by the fact that wealth seems to be more divided than formerly. We do not see such great places as Chatsworth, Alton Towers, Trentham, and Welbeck, now in course of erection. This age of great landed estates is gone—their dissolution has set in; but the work of our forefathers, who planted and embellished the surroundings of these great houses, still stand, and will stand for a long time yet. What they did they did well, and we may take a lesson from them in this, though we may not be allowed the scope they were privileged to have. This is the age of the middle class—the merchants and princes of commerce. Having been successful in business their first thoughts turn to a beautiful home, and for this end they call in the services of the gardener, and thus we see that increase of national wealth increases the demand for gardeners. There can be no doubt that a pure love of flowers has induced many to remain in the profession who would have been far more successful in other walks of life. Canon Hole's love for the Rose was intense, and the spirit which animated that gentleman is strong amongst gardeners. Some of the happiest moments of a gardener's life are passed in admiring his plants, which, after long and careful attention, have at length rewarded him by their beauty and high quality.

Of the four nationalities which together form the British people, Scotchmen in the past have been in the front as gardeners, this arising from their superior education and consequent ability, but Englishmen are beating up, if they are not already in the van. We see the Royal gardens of Windsor and Sandringham in the charge of a Welshman and an Englishman respectively, and if we glance down the directory the array of well-placed English names compare favourably with those of Scotchmen, whilst Irishmen and Welshmen are lagging in the rear.

We will now briefly touch on societies. At the head is the Royal Horticultural Society. From this Society, and from other minor societies that have been and are being formed throughout the country, gardening has derived immense benefit. Many of these latter are projected in the interest of one particular plant or flower, such as the Rose, Dahlia, and Chrysanthemum. While encouraging excellence of cultivation their annual exhibitions have been the means of inducing many to patronise horticulture when other means have failed to excite their interest.

Then come the mutual improvement societies, which exist in nearly all our large towns, for the purpose of improving young gardeners and for the general diffusion of horticultural knowledge, and as far as my experience goes they do it admirably. In these days, when prosperity is with us, and labour, skilled and otherwise, is agitated, we are led to inquire whether anything can be done to further the interests of the gardeners by means of combination, but we are confronted at once by great and insurmountable difficulties. Even were it possible for gardeners to combine, I do not see that it would mean success; on the other hand it might mean ruin. We should not forget that we are chiefly engaged in the production of luxuries which could be dispensed with, and when we remember the isolation of gardeners, their quiet, retiring, and unobtrusive habits, we may as well dismiss the subject from our thoughts.

With benefit societies the case is different. In this way we might do much to ease our path in the evening of our life. Gardening being in an unusual degree a safe and healthy occupation, we should join a benefit society devoted to gardeners only, and I am pleased to learn that there is such a Society in existence, and from long and careful consideration of their rules I can safely recommend "The United Horticultural Benefit and Provident Society" as worthy of the confidence of all gardeners, founded, as it is on the principle of thrift, and helping those who help themselves. The Gardeners' Royal Benevolent Society does not fill the place of a benefit society, as its name indicates; it is

more of a benevolent institution, doing admirable work in that direction, and well worthy of the support of gardeners.

Now in conclusion let us see what are the prospects and the lessons we may have learnt from a consideration of the past. We have seen that Scotchmen in the past by reason of their superior education and sound practical knowledge have held their position in the front with ease. This should teach us something for our guidance in the future. A good practical knowledge is a great thing, and will always count. But scientific knowledge in combination with a good practical knowledge will count for a great deal more. Let us not forget that compulsory education is the law of the land. Our Board Schools are turning out the men of the very near future with a much more advanced education than formerly. The labouring man of the future will be the equal of the schoolmaster of the past, and it behoves gardeners of all grades, especially young men, to see that they are not behind in the running. Closer attention to the study of such subjects as botany, geometry, and chemistry in relation to soils will be found to be of great assistance to gardeners, and will go far to elevate them. For our services to be in demand we must acquire a reputation for skill and sound knowledge. The history of our leading men shows us that there is no royal road to success; step by step they rose, increasing their knowledge as they went, until at last, the summit gained, they could turn and gaze beneath at those who were distanced in the steep ascent. Progress is the order of the day and the spirit of the age, if we do not go forward we go backward. Being constantly in contact with the most beautiful objects of Nature, gardeners live a healthy moral life, and their thoughts naturally have a high range; therefore in conclusion let me remind them of those well-known lines of Longfellow:—

"Lives of great men all remind us
We can make our lives sublime,
And departing leave behind us
Footprints on the sands of time.

"Let us then be up and doing,
With a heart for any fate,
Still achieving, still pursuing,
Learn to labour and to wait."

—CHARLES LEWIS, Gardener, Ivy House, Park Place, Cardiff.

NEW ROSES.—HYBRID PERPETUALS.

A CONSIDERABLE change has taken place in the new Roses introduced from France, for whereas formerly the Tea Roses formed a very small portion, amounting only to some six or seven, and between fifty and sixty Hybrid Perpetuals used to be announced, now the two classes much more nearly approximate in numbers, for this year we have twenty-one Teas and twenty-eight Hybrid Perpetuals. There is no doubt that the increased attention given to Tea Roses with us, and their increasing popularity, have reacted on the French raisers, and have led them to pay more attention to the raising of seedlings of this class than used to be the case. It is another curious instance of the law of demand and supply. Formerly, when Tea Roses were little cared for few were raised, now when so many are looking for them the supply is quadrupled.

It is no wonder that we look in the most placid manner at the lists of new Roses, when we find that of the twenty-four which stood highest in Mr. Mawley's analysis of Tea Roses exhibited in 1888 (I do not quote last year as it was so exceptional a season), there were only three which had been sent out since 1880, and there was not any of later date than 1833. The analyses given by Mr. Wilks in the proceedings of the Rose Conference tallies very much with this, for in the first twenty-four, where the voters amounted to seventy-nine, there were but three additions to the number of new Roses, and of these one obtained twenty, another twelve, and another ten votes, the highest number, A. K. Williams, having seventy-one votes, and these three varieties are all English raised flowers. No wonder, then, that we are not much excited by the amount of new Roses, no matter how glowing the descriptions may be. And withal we must see what our French friends try to tempt us with this year, and we find M. Eugène Verdier does not head the list as far as numbers are concerned this year, as that honour (?) falls to Levêque et fils, and his flowers are not so numerous as in former years, as he only announces five.

EUGÈNE VERDIER.

Abel Chatenay.—Vigorous plant of erect habit; flowers large and well shaped, brilliant currant red flushed with carmine.

Buffalo Bill.—This name seems to have taken with the French, for

I have seen several plants so named. Erect habit; flowers large, flat; colour deep rose. This is a form which has much gone out of favour of late years.

Laurent Carle.—Growth very vigorous and erect; flowers large, full, and well formed; colour beautiful carmine rose, very fresh in the colouring.

Leopold Vauvel.—Flowers very large, of admirable form, holding themselves well, very sweet scented; colour clear red, sometimes shaded very fresh.

Skobeleff.—Flowers large, well formed, rose, much shaded with lovely lilac; the buds are enormous.

LEVÊQUE ET FILS.

Duchesse de Dino.—Plant vigorous; flowers large, well formed; colour red velvety crimson, shaded with deep carmine.

Emile Bardiaux.—Plant vigorous; flowers large and well formed; colour bright carmine, shaded with flame colour and violet.

Laforcade.—Colour brilliant carmine red; plant vigorous.

Madame Thibaut.—Stout, very vigorous; flowers large, full, imbricated; colour tender satiny rose, shaded with bright carmine rose.

Martin Cakusae.—Plant vigorous; flowers large; colour bright carmine rose.

Maurice Levêque de Vilmorin.—Plant vigorous; flowers large, of a bright clear red, shaded with deep flame colour and brown.

LIABAUD.

Antoine Revoire.—Plant vigorous; flowers large and well shaped, colour red shaded with claret.

Mademoiselle Marie Magat.—Plant vigorous; flowers large and well formed, colour brilliant clear red.

Souvenir de General Richard.—Hybrid of Portland Rose; flowers very full, colour scarlet red shaded.

Vicomte de Lauziere.—Flowers very vigorous, large, well formed; flowers clear purple red.

KETTEN FRÈRES.

Antoine Schurtz.—A flower raised by the Hungarian raiser Geshe-mind, and sent out by this firm. Plant moderate; flowers large, full, and well formed, of the shape of Centifolia; flesh colour.

TESNIER.

Docteur Douet.—Plant vigorous; flowers large, well formed, of the most brilliant fiery red, deeper in the centre.

SOUPERT ET NOTTING.

Gloire de l'Exposition de Bruxelles.—Plant very vigorous; flowers large and well formed; colour purple amaranth, deeply shaded.

Oscar II. Roi de Suède.—Very vigorous; flowers large, well formed; colour carmine, flushed with vermilion, and shaded with brown. To this variety is appended the note that it was sent into commerce last May, and is now procurable in good plants at seven francs each.

PERNET FILS ET DUCHER.

Gustave Peganeau.—Plant vigorous; flowers extra large, full, cup shaped; lake red, with brilliant carmine.

LÉDÉCHAUX.

Jeanne Hély d'Oissel.—Plant vigorous; flowers large, well formed, of admirable shape; colour purple red, bright in the centre, reverse of petals purple.

NABONNAND ET FILS.

Madame Alice Allatini.—Plant very vigorous; flowers very large, nearly full; colour satiny ruby red.

PERNET PÈRE.

Madame Bertrand.—Plant very vigorous; flowers very large, nearly full, colour beautiful clear rose, the reverse of petals crimson red.

WIDOW SCHWARTZ.

Madame Chabal.—Very vigorous plant; flowers medium size, full, cupped, colour carmine rose with silvery sheen.

Souvenir de Gomot.—Plant vigorous, flowers large and well formed, globular, colour fiery red, centre deep velvety claret colour.

GUILLOT ET FILS.

Madame Renachy.—Plant vigorous; flowers well formed, colour clear rose with carmine centre, reverse of petals very tender rose.

DUBREUIL.

Marie Sage.—Plant very vigorous and free flowering, seedling from Hermosa, colour of China rose. To this a note is attached in the list I have before me. This Rose is stated to be a hybrid of Bengale, what is it?

MOREAU ROBERT.

Souvenir Grégoire Bordillon.—Plant vigorous; flowers large and well formed, colour bright scarlet red shaded with vermilion.

J. DUCHER FILS.

Souvenir de Rosieriste Jacobs.—Plant very vigorous; flowers very large, full, well shaped, colour bright cerise red, veined with bright rose.

I cannot say that this list is one to very much inspire us with hopes. Those credited with the greatest number are Messrs. Eugène Verdier,

Liabaud, and Levêque. These have all given us from time to time good Roses, although unfortunately they have been weighted with a vast number of bad ones. Many raisers, some of whom are new to us, give only one each, and it is possible that amongst them may be found a good flower or two, but the probability is that we shall see very few of them. The English Rose growers for sale have frequently wasted money, time, and space in propagating worthless things, that they have very considerably contracted their orders for new varieties, and of course amateurs never do, and I fancy the growers are in their orders more influenced by the names of the raisers than by the descriptions of the flowers. We may see some of them this season, and then be able to judge. *Nous verrons.*—D., Deal.

MARÉCHAL NIEL.

IN answer to "M. G. D.," page 108, I have seen Maréchal Niel Rose do most satisfactorily on a back wall in a vinery, but for my part I would rather keep the wall bare than run the risk of getting insects into the house.—S. SCOTT, Rathmore.

WILLIAM A. RICHARDSON.

I SEND you by post a box of W. A. Richardson blooms; they were cut from a plant three years old, grown in a pot and trained on the roof. The plant covers a space of 5 feet by 2, and is very badly cankered. It was pruned and placed into a house on the 10th of October last, the temperature being about 55° by night and 65° by day, and it has produced seventy-one flowers, in some cases four and five in a truss. They are a good colour, but the foliage is small, owing no doubt to the cankered stem. No mildew has appeared, and we cut the first bloom on the 20th of December, the enclosed being the last on the plant. I should like to know if any of your readers have had experience with it as a winter-flowering Rose, and if so with what success.—SUSSEX.

[The specimens we have received are highly satisfactory.]

GARDENERS OUT OF SITUATIONS.

I WISH to inform your correspondents that there is in Belfast a society for the relief of gardeners out of employment. It has been established several years, and is registered under the Friendly Society's Act. Members pay 2s. 6d. admission fee, and 1s. per month afterwards, which entitle him to 10s. per week for two months when out of place. If not suited at the end of the two months, by application he can have his case brought before a special meeting. No member is entitled to benefit till he has been two years a member, neither can any member receive benefit more than once in two years. Noblemen, gentlemen, nurserymen, and seedsmen may become honorary members by paying £1 per annum.

I am sure Mr. Dickson, Ormeau Park, Belfast, would have the full list of rules sent to any address; or, if desired, I will forward them for publication in this valuable Journal.—CORRESPONDENT.

[Please send the rules for our examination.]

I HOPE many of your gardening readers will communicate their ideas on the above subject, so that it may be seen to what extent the gardening fraternity concur in the suggestions thrown out by your correspondent "B." page 60, and other correspondents at page 118. This is the only means by which we shall ever secure a self-help society to render assistance to those brothers of the craft who may be out of situation and requiring help. My idea is gardeners should combine together for their own interest more than any other class of working men, but I am sorry to say they are far behind the times in this respect, but as such a favourable opportunity presents itself now it should not be lost. I notice your correspondent, "R. M." page 118, is inclined to think it is but an old cry "so many out of place," for he states it has been the same throughout his forty years' experience. I am inclined to think "R. M." is over the stile and through the wood, and has landed there without the aid of a self-help society, and consequently he thinks others might do the same. As I have only seen twenty years' experience, I cannot go back so far as "R. M." to form an idea, so I will mention the experience of two good old gardeners who can boast of over forty years trudging in gardening, and they say they never knew so many gardeners out of place as at the present day, and they attribute this to so many of our once noble gardens being closed.

"R. M." again says, "'B.'s' ideas respecting gardeners going into the nursery and thereby causing an injury to the permanent staff is a ridiculous assertion." It is a well-known fact, however, that if gardeners who are out of place did not go into the nursery, nurserymen would have to employ a much larger number of regular hands, and pay them higher wages. Now if we had the self-help society, the gardener would not enter the nursery unless he received the same wage for the same amount of work as that of the permanent hand. I shall be most happy to subscribe to any society which may be formed for helping gardeners.—ALFRED BISHOP, Westley Hall Gardens.

It is not long since I saw one of those who are sometimes termed "frozen-out gardeners," so that I have read with the greatest interest the correspondence that has been going on in the *Journal of Horticulture* recently. I am glad to see that there are gardeners in favour of a move being made in some way to help their less fortunate brethren. I should be only too glad to assist with my mite whenever it is required, and I know others who would be glad to give their support as far as it is in their power. My experience seems to have been much the same

as "B.'s." I hope this matter will be taken up, I think it will find plenty of supporters.—W. J.

AURICULAS IN SCOTLAND.

The early part of winter being so mild Auriculas started into growth about the first week of the year, fully a month earlier than usual. During the whole season, since the plants were placed in their winter quarters, they have looked healthy and well, and notwithstanding the absence of frost they have required little water. A large number of the plants are now so far expanded that the truss is seen. In my own collection Prince of Greens was the first to give promise of a bloom, then Acme, then my own Mrs. Sinclair, and now there is a host of others. From the advanced state of growth among the plants I anticipate an early bloom, even though frost come farther on. There has been only one death in my whole stock, and my friends write me that they are much in the same condition. Young growers should notice that if at this time any plant does not show signs of expanding its foliage it should be examined, and the chance is decay will be found in some part of the stem. When there is no frost the plants should be getting more water, and the surface soil should be stirred without disturbing the fibres if possible, and where the soil has sunk in the pot fresh soil should be added. I have always held that top-dressing the whole stock is a waste of time, and now many growers are of the same opinion.

The number of Auricula houses is increasing in Scotland. It is the most satisfactory way of growing the plants, as one can get amongst them whatever the weather be. I have been exceedingly pleased to see from requests to myself and other growers for the older varieties that the idea of growing only a few of what are called the finest kinds is not spreading in Scotland. From my correspondence I learn that there are many seedlings on trial which are expected to take good places among our best flowers. The Scottish Primula and Auricula Society is to hold their Show in Dundee this year instead of in Edinburgh, where it has been hitherto held. It is very likely that a Narcissus section will this year be added, which will be an additional attraction. I hear a prize is to be offered for the best self seedling stage Auricula (named) entered for competition for the first time. It is expected that the Show in Dundee will be a thorough success.—JOHN MORRIS.

SCENTED FERNS.

DRYNARIA (POLYPODIUM) WILLDENOVII.

It was recently announced in the London daily papers that at one of the Saturday meetings of the Royal Botanic Society at Regent's Park "an interesting sweet-scented Fern was exhibited. The perfume, which closely resembles that of fresh hay, is retained after the frond is dry, and lasts for many months, if not years, imparting its fragrance to anything in contact with it. The Secretary thought it might be grown as a source of perfume by amateurs, if not commercially. As yet it appeared to be little known in collections of exotic Ferns." This paragraph seems to have awakened the interest of a correspondent of a metropolitan paper, who produces the following remarkable article, but whether it is written in a satirical and sarcastic vein, or in sober seriousness, we must leave our readers to discover. It seems to be an age for calling public attention to extraordinary plants. Lately we have had "the Weather Plant" brought into great prominence by a scientific report from Kew, and now the Regent's Park garden produces a rival phenomenon in the shape of a "Fragrant Fern."

But let us see what the writer named has to say on the subject. "At certain times and seasons in the history of the animal and vegetable kingdom there are plants and animals, birds, beasts, and fishes which have, as it were, 'greatness thrust upon them,' in the sense that wholly unsuspected qualities of attraction and gratification are discovered in their lives, habits, and structure. Thus for centuries there lived in harmless and blameless obscurity a tiny shell-fish, the murex, by the shores of Tyre. No one minded him as he clung to his Syrian rock, and as he was not good to eat he was let severely alone. One day, however, a fisherman drying his linen garments by the sea-shore happened to crush the little murex, and, behold, his fisher's robe was straightway dyed a deep purple, which no cunning could wash out. The good folk of the district saw at once that there was distinct artistic and commercial value in the murex, and after a few al fresco experiments learnt the great secret of the Tyrian purple. Henceforth the murex and his crimson juices became part and parcel of the symbol of imperial sovereignty, and ever since his august colour has ruled the world. The cochineal insect, the musk-rat, and the leech as a phlebotomist, are among similar examples of discovered charms and values; but our present subject deals with the latest developed attraction of a highly respectable member of the group of cryptogamic plants in the shape of the sweet-scented Fern from the Royal Botanic Society's Garden, which was exhibited by the Secretary, Mr. Sowerby, at the meeting of the Society last week. Ferns have always been mysterious puzzles to mankind, especially in the inaccurate days when there was much strange talk of their so-called 'seeds,' which are now called 'spores.' We know that Shakespeare makes Gadshill say, 'We have the receipt of Fern-seed, we walk invisible,' and Ray ridicules Tragus for spreading linen cloths on the ground to catch the seed of Ferns on the eve of Midsummer Night, when, as Ray properly observed, it would be indeed astonishing if any fell, seeing that it is not mature until the

autumn. However, neither the early botanists nor the Elizabethan dramatists speak of a sweet-scented Fern—though there is one English variety with a slight odour—and they would be interested to learn what has been the most recent exploit of that fine luxuriant Fern known as '*Drynaria Willdenovi*,' which came over to us some twenty years ago from its native land of the Mauritius, and lived in the Botanical Gardens for many a long day without attracting any special attention. It seems that, about a year ago, some observer with an acute sense of smell came into the house where are the broad 'vandyked' leaves of this *Drynaria*, and asked, 'What is it that smells of hay so nicely?' Sundry scientific minds were quickly on the scent, and they soon ran the hay-smelling Fern to its native pot. The scent is unmistakable: it can be caught from the decaying leaves, but comes out strongest and best when the leaves are thoroughly dried, and, as it were, made in a natural 'pot-pourri.' If a few of the long strong stalks—down which the foliage, resembling 'adder's tongues,' runs for about a foot—are gathered and placed in a room, they will soon 'bring the scent of the hay' over the domestic footlights, and, on the whole, our visitor from the Mauritius has made a sudden and successful bid for a perfumed popularity, and promises to do well in the character of the Fragrant Fern. The Secretary thought it might be grown as a source of scent by amateurs, if not as a commercial investment, and altogether this amiable member of the famous family seems likely to make a name for itself.

"The curious part of the story, however, is that it is only of comparatively recent date that this Fern thought of going into the perfumery business. For years it was too sleepy or too indolent to express its Mauritian soul in giving forth the subtle essence of English new-mown hay. What woke it up? Who whispered to it of a new triumph? What new vitality from the watering-pot crept through its slender, wiry roots and up its dark brown cylindrical stem, so that it suddenly quickened into a new grace? The Royal Botanical Society and the Kew Gardens authorities, who not long ago wrote to ask Regent's Park for one of these plants, may say what they like about it, but our own view, confirmed by a recent personal interview with the Fern itself, is that the new effect is entirely due to the intruding sparrows, who for years have lived and built their nests in those lordly glass houses in Regent's Park, at which, at all events, nobody is inclined to throw stones. There is a prosperous colony of eternally chattering, twittering, gossiping sparrows who have taken a fancy to semi-tropical temperature, and who live and nest amongst giant Palms and the Eucalyptus—another plant, by the way, that has of late years become famous in the line of *materia medica*—and such vegetation as they have scant right to roost upon. These impudent little birds no doubt told the sleepy tropical plants all about the perfumes of the English flowers, and, it may be, went so far as even to 'chaff' a big Tree Fern, whose ancestors may have embowered a woolly elephant or a five-toed horse, with being altogether beaten by our Roses, Violets, and Mignonette. And their scornful gossip came to the *Drynaria Willdenovi*, and they chipped out, with the audacity peculiar to a London sparrow—that very gamin of birds—'Look here, old *Dryasdust Drynaria*! why can't you smell as our plants do?' Then the heart of the Mauritian awoke within him, and he said, 'Sparrows, you are flippant but suggestive; I incline to agree with you, and I shall endeavour to become at once fragrant and famous.' Certainly he has fairly accomplished both tasks, and taken away the reproach of his brethren among the exotic Ferns. It is but right to state that this theory is as yet wholly unsupported by any scientific evidence, but, pending the voice of the scientists, we stand by our sparrows. In a smaller house adjoining the palace 'where sparrows build' may be found another curious example of a perfumed plant, or rather of one that was in its early youth, like many of the human family, given to costly odours. It is a native of Brazil, and is called the *Geonoma Pamila*, or 'Scented Palm,' and when it was a soft green young thing it used to give forth a strongly perceptible fragrance as of Violets. Some way or other, however, as it got old it got sulky, and did not seem to care so much for the niceties of its toilette; and now it has just as it were an echo, and no more, of its pristine perfume, and you must climb up and get quite close to it to catch that echo. All the same, mindful of the poet's lines, 'Odours, when sweet Violets sicken, live within the sense they quicken,' it certainly does its best to recall and suggest the peculiar charm of its early days, and deserve the proud title of the 'Scented Palm' inscribed on its recording stick. There are no sparrows in the place where this Palm lives, which may account for its indolence; but no doubt some intelligent cheeper will find his way to the hot, moist atmosphere of this little Eden of Orchids, and by 'winged words' warm up the *Geonoma* into happy rivalry with the Mauritian Fern, which is just now so happily busy distilling essence of hay."

FRUIT FORCING.

MELONS.—Young plants have progressed favourably. Make a ridge in the Melon house the whole length of the bed, about 2 feet wide at

the base, with the top flattened so as to give a depth of 10 to 12 inches, which is preferable to hillocks, the soil being made rather firm, and when warm the plants may be turned out, firming it well about the roots, and bringing it up to within an inch of the seed leaves. The plants may be placed 2 to 2½ feet apart, the leading or primary shoots being taken up without stopping until fully two-thirds the distance they are intended to travel is reached, then pinch out the point of each. When three or four lateral joints are made the points should be taken out. Some varieties will show fruit freely on the first laterals, and as early Melons are a consideration let them remain, taking out the point at a joint above them, but not stopping in this case until the flower is fertilised. To allow all the laterals to remain would much overcrowd the foliage, therefore rub off every alternate one whilst they are quite young. After stopping the first laterals the succeeding growths will show fruit at the second or third joint. Train the growths thinly and regularly, so that every part has full exposure to light. The plants will require but little water as yet, nevertheless maintain the soil in a moist state, avoiding saturation. Sprinkle every available surface in the morning of bright days, and again at closing time or early in the afternoon. Ventilate carefully, avoiding currents of cold air. Some hexagon netting or scrim canvas placed over the ventilators will break the force of cutting winds. Maintain the night temperature at 70°, falling to 65° in the morning, 5° less in severe weather being better than seeking to maintain the higher temperature by sharp firing, 75° by day, rising to 80° or 85° from sun heat; keep bottom heat steady at 80°. Shift later sown plants into larger pots or add soil as the plants advance, stopping those for frames at the second leaf, but not those for trellises, placing a small stick to each for support.

Melons in Pits and Frames.—With the shoots trained over the surface of the beds, the plants, being stopped at the second leaf, will produce two shoots, and these in turn being stopped will result in four shoots with smaller ones. The weaker should be rubbed off, and two of the strongest trained to the front and two to the back of the frame or pit. Rub off all laterals to a distance of 6 inches from the stem. This will keep the collar clear—an aid against canker. Stop the principal shoots when within a foot of the side of the pit or frame, and thus throw vigour into the laterals, which will show fruit at the second or third joint, stopping them at one joint beyond the fruit. Cover the lights with double mats at night and see that linings are regularly attended to, renewing the old as required. About a fortnight before it is desired to make the beds the dung and leaves should be thoroughly incorporated. In a few days it will be seen whether there is sufficient moisture to produce decomposition, fermentation being the result. If not, turn the whole, sprinkle with water so as to moisten the mats, and when there is a good heat turn it again outside to inside and *vice versa*, two or three turnings being required at intervals of about four days. The bottom heat of fermenting beds should be 85° to 90°.

CUCUMBERS.—Examine the plants in bearing once or twice a week, removing bad leaves and exhausted growths, thinning the shoots, stopping and removing old and deformed fruits. Overcrowding and overcropping must be carefully guarded against, as they are highly prejudicial. In securing young shoots to the trellis do not tie them in too tightly, but allow room for development. Plants that have been in bearing some time should have the surface soil removed and have warmed fresh soil added. Turfy loam with a fourth of well decayed manure will answer for Cucumbers and Melons. However, we prefer turfy loam without any admixture of manure, impart vigour by rich surface dressings or liquid manure. A sprinkling of the advertised fertilisers we find extremely useful, being careful not to apply them too freely and too often. The bottom heat should be kept steady at 80°, the night temperature 65° to 70°, 5° less in severe weather; 70° to 75° by day, rising to 85° from sun heat, closing early in the afternoon, damping the pathways on bright mornings and at closing time.

For young plants hillocks or ridges should be formed as described for Melons. Afford the same temperature as advised for older plants. If the sun be powerful, and the plants show indications of flagging, shade them for a few days. Attend to dung-heated frames with linings as required, protecting at night as advised for Melons. Do not apply more water than is needed to keep the plants gently growing. Where red spider has appeared on winter fruiting plants coat the pipes with sulphur and lime in equal parts, heating the pipes to as near boiling point as possible for a couple of hours on a calm evening, taking care that the temperature of the house is not more than 80° to 85°, and then allow the pipes and house to cool down to their regular temperature. The foliage should be thoroughly dry. The same process may be repeated the following evening, and is generally effectual, the mixture being applied whilst the pipes are hot.

PEACHES AND NECTARINES.—*Earliest Forced House.*—Syringe the trees every morning and afternoon, in order to keep insect pests from attack or to dislodge them. If, however, the weather be dull, the syringing must be practised early in the afternoon, so that the leaves may become fairly dry before night, or if that does not take place the afternoon syringing must be dispensed with, damping the paths and borders instead, as keeping the trees dripping with water through the night causes weak growth and thin foliage. See that the outside border is well protected from the cold, and water the inside border with liquid manure, which will much assist the fruit in swelling, especially in the case of weakly trees long subjected to repeated forcing. Vigorous trees will not require any stimulants, excessive vigour being unfavourable to the fruit safely passing the stoning process. When the fruit is the size of small marbles thinning may be commenced, but remove a few fruits

only at a time, first removing those that are badly placed. Disbudding must be followed up, taking care to leave a growth at the base of each bearing shoot, and another at its extremity, or, at least, level with the fruit. The shoots retained for attracting the sap to and supporting the fruit should be stopped at the second or third leaf, but the basal shoots must be trained to take the place of those now bearing fruit. Shoots upon extensions must be left at 12 to 15 inches distance apart to form the bearing shoots of the future. It is a great mistake to crowd the trees with growths that cannot be fully exposed to light and air, but maintain an equal balance of growth throughout the trees.

Second Early House.—Continue fertilising the flowers gently, distributing the pollen by shaking the trellis or drawing over each flower a camel's-hair brush, or other means of distributing the pollen. Lose no opportunity of admitting air, avoiding, however, cold currents, and leave a little ventilation constantly at the top of the house. The night temperature may be maintained at 50°, 5° less on cold nights, 55° by day artificially and 60° to 65° from sun heat, not allowing a rise above 65° without a free circulation of air.

Houses Started Early in February.—Trees started early in the month are swelling their flower-buds rapidly. Syringing must cease when they show colour. Maintain, however, a good moisture by damping paths and borders two or three times a day as the weather may dictate, avoiding a close stagnant atmosphere. If the flowers are numerous thin them by rubbing the hand downwards on the under side of the shoots, which will strengthen the remainder, enabling them to set better. Examine the trees closely, and if there be any aphides fumigate with tobacco, so as to destroy them before the flowers expand. Continue the temperature at 40° to 45° at night and 50° by day, and 60° to 65° from sun heat with free ventilation. Allow a little ventilation constantly at the top of the house.

STRAWBERRIES IN POTS.—The first plants have set their fruit. Remove all badly set or deformed fruits, leaving from four to half a dozen of the most promising fruits to each plant, and aid their swelling by liquid manure. The temperature should be 60° to 65°, advancing to 75° by day with moderate ventilation. Avoid drying currents of air, as they injuriously affect the swelling of the fruit. Examine the plants twice each day, giving water to such as need it, and in sufficient quantity to show at the drainage. See that succession plants are kept free from aphides, fumigating and repeating if necessary before the flowers open, so as to have them perfectly clean. Introduce more plants, so as to maintain the succession. Sir Joseph Paxton, Sir Charles Napier, President, Auguste Nicaise are admirable sorts. British Queen and other late sorts may now be started, bringing them on, however, very gently.

THE FLOWER GARDEN.

Hotbeds, Propagating.—A sweet and fairly brisk bottom heat, generated by a bed of leaves and stable manure, is of the greatest assistance to the propagator, this being far preferable to the dry heat from hot-water pipes, whether for seed-raising or striking cuttings. This season the leaves especially are much saturated, the rainfall being heavy and continuous, and it will be found they are slow in starting, and will retain heat for a short period only. They are also certain to be badly infested by small white and black slugs, for which a close watch will have to be kept, or much injury may be done in one night. If the manure is mixed with the leaves and all thrown up into a conical heap, being also enclosed in dry straw litter, all will soon become equally hot, much rankness and moisture being got rid of in the course of about ten days, one, or at the most two, turnings inside out being given. It is a good plan to cover the hotbeds when made with about 6 inches of cocoa-nut fibre, this being very clean for plunging in, and the slugs do not like it. When the bottom heat is obtained solely with the aid of hot-water pipes there ought to be a good depth of clean plunging material provided, nothing being better than a depth of 12 inches or rather more of cocoa-nut fibre, the next best thing being sawdust. If either material becomes very dry, and this is liable to happen quickly, it ceases to conduct heat properly, therefore keep it frequently and uniformly moistened.

Sowing Begonia Seed.—All minute seeds germinate more surely when sown before the sun gains much power, a dry heat or much sunshine usually proving fatal to the delicate growths. The earlier, therefore, Tuberous Begonia seed is sown the better. Fill either heavily drained 6-inch pots or pans with light soil, nothing being better than a mixture of two parts of either good fine leaf soil, or failing this, peat and one part of fine light loam, with a sprinkling of moderately coarse sand. The surface should be made very smooth and even, and well moistened a few hours prior to sowing the seed. Silver sand on the surface not unfrequently does more harm than good, the seeds germinating more surely when sown on the surface and not covered in any way. Plunge the pots in a brisk bottom heat, some provision, if need be, being made to exclude worms; cover closely with squares of glass, and shade heavily till the tiny plants are seen, then gradually expose to light, taking care, however, to ward off bright sunshine. Not unfrequently the soil keeps sufficiently moist without the application of water till the seedlings appear, and in this case a great percentage of them are reared. If from any cause the soil becomes at all dry, the safest way of moistening is by partially dipping the pans or pots in warm water, damping from the surface, no matter how carefully it is done, being apt to dislodge and spoil the seed. Plants raised early from seed may be grown to a serviceable size before bedding-out time arrives.

Bedding Lobelias.—The bulk of these are nowadays raised from seed, the leading seedsmen being in a position to supply superior and

reliable strains. The seed ought to be sown at once, and being very small must be treated much as advised in the case of Tuberous Begonias. In this instance the seed is much cheaper, comparatively large packets being distributed, and as a consequence it is often sown far too thickly, the result being wholesale damping off. Large square pans are very serviceable for raising seedlings generally, as these can be set closely together, and also more readily covered with squares of glass. If there is a good stock of old plants of any good variety these must be kept out of a dry heat, or they will run to flower quickly, a moderately warm greenhouse best suiting them. What are wanted are abundance of either sappy shoots, which strike quickly in gentle heat, the tops soon being available for making into cuttings, or the plants may shortly be pulled to pieces, every division being already furnished with roots, always supposing too much fire heat has not been given, these divisions furnishing cuttings, and in time develop into extra fine plants.

Verbenas.—Seedlings of these are of somewhat irregular growth, and are principally used in mixed beds. The seed sometimes germinates slowly, and for this and other reasons may well be sown now. It ought to be very lightly covered with fine soil, and being duly plunged in a brisk hotbed covered with glass, well darkened, and the soil kept uniformly moist, every sound seed ought to germinate in less than a month. The seedlings being grown on quickly in pans or boxes of good soil, all may be propagated from prior to placing in cooler quarters. Insect-infested much-starved Verbena cuttings never develop into good plants. Those taken from clean healthy plants growing in a moderately warm house or pit, on the contrary, strike quickly and grow strongly.

Antirrhinums and Pentstemons.—Early raised seedlings kept growing without any serious check will flower strongly in the open borders the same season, young plants usually producing extra fine spikes. Beds of either in separate colours, or in mixture, are very effective, and are a good change. Both should be sown in pans and not very thickly. The seed of the first named is somewhat small, and must either be sown on the surface or only very slightly covered. The Pentstemon seed being rather larger should be pressed into the surface of the soil, and scarcely covered with fine soil. Antirrhinums are most liable to damp off badly in the seed pans, and it is therefore advisable to avoid overhead watering, and also to place the pans on a shelf in a somewhat lower temperature a few days before they are pricked off.

PLANT HOUSES.

Leoras.—Young plants that were rooted towards the end of August and have been kept slowly growing in a temperature of 60° to 65° may now be placed into 5-inch pots, in a compost of equal quantities of loam, peat, and sand. If practicable plunge the pots in a bottom heat of 75° to 80°, and do not allow the temperature of the house to range lower than 65° at night. Plants to be grown into specimens and in 5-inch pots may have the points taken out of their shoots, and placed into pots 2 inches larger. Give the same treatment as the younger plants, but two-thirds of peat to one of loam may be used. Larger plants must be thoroughly cleaned if they need it, slightly pruned back, and when they start into growth repotted.

Vincas.—Small plants are useful where stoves have to be kept gay throughout the year. A few plants may be started into growth to yield cuttings. For early flowering plants that were rooted last year are useful. These may be pruned well back, the roots partially reduced, the plants started into growth, and allowed to come into flower without pinching.

Clerodendron fallax.—Plants that were grown strong last year and well ripened may be pruned and started into growth in brisk heat. They break freely if they have been cared for during the period of rest, and not kept in a lower temperature than 55°. When they have started into growth the plants may be turned out of their pots and the roots carefully reduced one-third, repotting in loam, leaf mould, one-seventh of manure and sand. They will need careful watering, and if allowed to flower without pinching will produce large heads early in the season. Place young plants of *C. fragrans* into 5-inch pots, and insert cuttings singly in small pots.

Clerodendron Balfourianum.—When the earliest started plant has made growing shoots 2½ to 3 inches long slip off the required number with a sharp knife, and insert them in sandy soil and cover them with a bellglass. If given a good watering and plunged in bottom heat they will soon form roots. Pot them singly; replunge them for a start. These will make splendid plants in 6 and 7-inch pots for training round stake for either stove or conservatory decoration. Another old plant may be introduced into heat as well as a few young ones trained round stakes for the decoration of the side stages of the stove.

NOTES ON BEES.

STRAINING HONEY.

As the honey passes from the presser to a pitcher beneath no time is lost until it is poured into the uppermost sieve of a series of two to four (as may be required), and at last into a net or a muslin

tapered bag suspended by hooks from the iron rim. From this bag it passes into the storing jar, and all within an hour or two from the time the comb was taken from the hive. The more speedily the work is done the greater is the aroma and quality of the honey preserved, being superior to that long exposed and artificially ripened. The longer honey is exposed to the atmosphere the more watery it becomes, with a corresponding loss of flavour and aroma.

RIPENING HONEY.

This is an objectionable term often used, but misunderstood and abused; and when we read about it we are much amused. We are told that in order to ripen the honey in the hive the bees store it at first in the body of the hive, then carry it up at night to the supers, when the heat of the hive expels the excessive vapour. I have omitted inverted commas from the above, as I write from memory only. Let us analyse the statements. Hives that were reputed to do so, increased in weight 10 lbs. daily, and the frames of the standard size ten in number. Each frame (as they are narrow) when sealed holds about 6 lbs. of honey, or rather under that; when unsealed less than 3 lbs. The excess of water is about 1 lb to every 5 lbs., and requires at least five empty but combed frames for one day's work, leaving five frames for brood, pollen, water, and honey for the internal economy of the hive, which cannot leave more than three for brood, not more than space for five days' egg-laying, and in many cases considerably less, and yet there is no secret about the number of eggs laid by the queen. I wonder how the authors of these statements can reconcile them. I have given the figures and statements as wide an allowance as possible to assist a reconciliation, but fail to see how it can be done. The fact is, a hive likely to gather 10 lbs. honey daily requires all the ten-frame space for the internal economy of the hive irrespective of placing honey temporarily therein in half of the frames.

How, then, is the surplus water extracted from the honey? From the moment the bee begins to sip the honey from the flower it expels the water as it desires; its formation enables it to do so. Stand so that the bee is between you and the sun when it is sipping honey or syrup, and you will soon see the water being discharged, while the honey is retained, is carried home, and stored directly in the upper chambers, not a drop being placed beneath. As the bee regurgitates the honey into the cell, packing it closely to expel all air, the surplus water not previously expelled for the purpose of enabling the bee to perform its work rapidly, rises to the top, and is sipped off by the bees. If Heather or other thick honey required to have the water it contained removed while in the body of the hive, it would take the bees two or three days to carry up what they gathered in one day.

Frequently I have had swarms placed into empty hives at the Heather, and in less than twenty-four hours sealed combs of the finest quality, as such always is, by what other process than I have described could the bees extract the surplus water? The steam we see issuing from the entrances to the hives, and the water or condensed steam upon the landing boards when bees have been getting honey, is expelled in the same way. It is simply absurd to say it is the heat of the hive that expels the surplus water; it is the mechanical process of the bee combined with the law of the lightest matter coming to the top, not unlike the superfluous vanity and airs of foolish people, which for a time appear prominent.

BEEES FOR PROFIT—IN THE HEATHER DISTRICT.

"Will 'A Lanarkshire Bee-keeper,' who has had much experience and been very successful with bees at the Heather, kindly inform me how I should manage my bees? They unfortunately are in a poor district for Clover, having only about as much as will keep them alive till the Heather is in bloom, of which there is abundance, and upon which I depend for my surplus. My bees are pure Carniolians. I have swarms in May, and I use the Lanarkshire tiering hive. Would not the swarming system be the most profitable course to pursue?—W. H. B. K."

"W. H. B. K." appears to be in a favoured district for Heather,

as well as a favoured spot for bees in spring, as his May swarms prove, which is the time to have swarms so that all may be in the best condition to take advantage of the Heather, which can scarcely fail, unless the months of June and July be extremely unpropitious. In order to have all in the best of order, the queens of the first swarms should be deposed and a young but fertilised one introduced. If possible select all such queens intended for stock purposes from a full strength hive. Although I differ in some respects from "A Hallamshire Bee-keeper," I never knew a full strength hive that changed its queen without swarming other than a profitable one. It must be observed that by cultivating the swarming system two-thirds more hives than there are stocks must be kept in readiness. This may be considered extra outlay, but then excessive numbers of hives during winter are unnecessary, and is undoubtedly making and taking most from a few. I will throughout the season give some practical hints on preparing and taking bees to the Heather. Meanwhile be sure you have your hives constructed properly for their removal and manipulation. I can prepare any hive I have for the journey in a few seconds if the supers are on, and in not more than five minutes if not.

ARTIFICIAL HEAT.

If I remember aright it was the Rev. Mr. Taylor that recommended artificial heat to advance bees in spring by plunging the hives into a hotbed or wrapping them with hay bands. The above appeared in the *Cottage Gardener* more than thirty years ago, and subsequently in the little manual, "Bee-keeping for the Many." Fifteen years ago I wrote an article describing how to heat and manage bees by the aid of hot water, having for long before that time employed hot water as an agent in pushing bees forward. From my instructions several apiaries were constructed on the hot-water principle. One of these was at Greenock, whose owner considered it a great advantage; but so far as my experience went there was in the end more loss than profit, and I would caution the beginner against it, more so as it has appeared in a contemporary under the heading of "A New Departure," although in reality an old thing revived, is likely to cause a sensation for a time, after a good sum has been lost on the experiment. The same journal, too, recommends peameal inside the hive, not unlike what I have taught and practised for nearly forty years.

BEE FLOWERS.

There is an unusually fine display of Snowdrops in many places, but mark the difference with Aconites. I have only two blooms instead of hundreds. Who can explain the cause? Is it owing to the weather last year?

PORCH ARRANGEMENT.

"Permit me, through the medium of your Journal, to thank your correspondent, 'Lanarkshire Bee-keeper,' for his answers respecting the Lanarkshire hive. I would further be obliged by his informing me how the various parts of the porch arrangement is attached to the hive? How is the zinc fastened to the top of the stand, so as the slide will work smoothly? Is the inner lid of the hiving box made of laths, or is it a solid piece of wood, and are the strings attached to the ends of the lid?—J. D. L., Northumberland."

Porch arrangements are various. After the porch is made to fit accurately the front of the hive I attach it by a pair of butt hinges, substituting a brass pin for the iron one of the hinge. By taking out the pin the porch is easily removed when wanted. Many porches are made by far too low, marring the bees when entering the hive. They should not be less than 7 or 8 inches, and to come right over the alighting board. This is of far more benefit than any top covering. The breadth should not be less than 4 inches

ZINC FOR HIVING BOX.

In the "Lanarkshire" storifying hive it is better when using the hiving box to separate the hive from the stand. In the others the zinc with its frame and shutter is in one piece, which slides out

or in as wanted, and the hiving box is made so as to take its place. I am not sure if I understand properly which hiving box is meant. If the one referred to above the lid is of three pieces pivoted at the ends, and about half an inch from the edge; these are attached to a frame with staples, and a wire keeps them closed until admitting the bees to the hive. If the upper hiving box the lid must be of the lightest material, cleated and close. It is to this one that strings are attached, so as to prevent bees being crushed. If a joint or two are left open for carbolicised paper to pass between, a few minutes suffices to cause the bees to retreat to the hive proper.

—A LANARKSHIRE BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

William Strike, 62, High Street, Stockton-on-Tees.—*Catalogue of Vegetable and Flower Seeds, 1890.*

John Watkins, Pomona Farm, Witherington, Hereford.—*Descriptive Catalogue of Seed Potatoes.*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

United Horticultural Benefit and Provident Society (J. E. P.).

—Mr. W. Collins, 9, Martindale Road, Balham, London, S.W., is the address of the Secretary of this Institution, and it would perhaps be advisable for gardeners as a body to copy it for subsequent reference.

Palms for a Table (J. G.).—The following are graceful Palms adapted for the purpose you name:—*Cocos Weddelliana*, *Geonoma gracilis*, *Thrinax elegans*, *Phoenix rupicola*, *Kentia australis*, *K. Belmoreana*, *K. Fosteriana*, and *Phoenix tenuis*.

Netting for Fruit Bushes (H. S.).—The method you propose is safe and good. It has often been recommended in the *Journal of Horticulture*, the last occasion not being very long ago. No injury will occur from the contingencies you mention, but it is advisable to have the sides of the enclosure moveable for the admission of birds after the fruit is gathered, and so long as they do not attack the buds. We know of many such wired enclosures as you propose erecting, and they answer their purpose well.

Dendrobium nobile not Flowering (W. R.).—Growths in place of flowers is a consequence of the imperfect ripening of the pseudobulbs, the plants being kept at too great a distance from the glass, and not having sufficient light with a reduction of moisture so as to harden them. As the growths reach maturity withhold the supply of water, removing the plants into a cooler and drier atmosphere, with full exposure to light and sun, in order to thoroughly ripen them. Water should only be given during the resting period to prevent shrivelling. A temperature of 50° artificially is suitable during the resting period. All that is wanted to restore their floriferousness is to secure a good growth and ripen it thoroughly.

Hard and Soft Putty (M. T.).—A little white lead mixed with putty will make it set hard in a few days; but gardeners never allow the use of that old kind of putty in these days, because once it gets dry they can hardly cut it when repairs or alterations are to be made afterwards. We have seen a good glazier break four squares of glass trying to mend one broken one, besides spending an hour and a half at the job, which a mere lad could do in five minutes, and without any breakage, if proper putty had been used in the first instance. Hothouse putty is made with whiting pounded down and sifted very fine, and boiled linseed oil, making it into dough as the bakers do their bread; the more the dough of putty is worked the better it will be, and it should be at least ten days old before it is used; in that time a large lump of it will "sweat"—that is, slightly ferment, which is necessary to give it the

proper adhesive power. When this soft putty, as it is called, is allowed to dry thoroughly before it is painted over, it will last as long as the hardest white-lead putty, and at the end of twenty years be soft enough to be cut away with a knife. If, therefore, you wished to remove your greenhouse at any future time, you could easily take out the glass, pack it in boxes, and the timber work could then be handed and packed without the risk or annoyance of breaking the glass.

Pruning Apple Trees (Golden Spire).—If you do not read more carefully than you write you will be certain to overlook what is printed for information. You say, "We planted trees in November, 1889, and now in February, 1890, they appear to have been cut back before we got them from the nursery; they appear to have plenty of shoots on for forming a tree." This is a very curious sentence. If the shoots appear at the present time as cut back before they left the nursery, surely they must have been shortened when they were received from there in November, 1889, and in that case they have not had time to make "plenty of shoots for forming a tree." If you can enable us to understand what you wish us to know, and make clear the actual condition of the trees, we will readily advise you how to proceed. You say you have "Writes" Essay. If you will refer to it again perhaps it may be "Wright's;" and, if so, you will find, on page 79 onwards, that when sufficient branches have formed for the framework of a tree the less they are shortened the better for the production of the greatest number of fruit buds, and an illustration is given on page 81 of the effect of the simple method of pruning described; also on page 18 you will see half of a bush tree as it should be pruned, and the other half showing the crop of fruit that follows in favourable seasons.

Fruit Trees on Walls (T. S. R.).—As your letter suggests the wall contains fissures in the joints, by all means unfasten the trees and have the masonry well pointed. If it is a stone wall you may wash it with lime toned to a darkish tint with soot. This may be done as soon as convenient after the leaves fall, and the trees can be pruned and secured to the wall as soon as the mortar is set, or before growth commences in the spring. It is not necessary to remove the branches every year, though the fewer and narrower the shreds are the better, and care must be taken that no ligatures are allowed to bind too tightly round the branches. Some gardeners unloose Peach, Nectarine, and Apricot trees in the autumn, and prune and secure them to the walls in spring, as by this means the swelling of the buds is sometimes a little retarded. Trees and walls may be advantageously syringed in winter with a solution of soft soap into which a quarter of a pint of petroleum is well mixed with each three or four gallons. This should be done before the buds swell in spring. Earwigs can be caught with flower pots containing moss or hay, or with hollow stems of beans, or any others of the same nature.

Vines and Frost—Cropping (M. B.).—We do not know how many degrees of frost Vines will endure without injury. Very much, we apprehend, would depend on the maturation of the wood. We have not known Vines on walls in the open air in the south of England to be injured by frost even when the mercury in the thermometer has almost fallen to zero. If there is nothing in a vinery besides Vines, and the wood of these is well ripened in the autumn, they will not be injured by frost in winter if no fire heat is employed; but we have known something else to be injured under the circumstances—namely, the pipes that are provided for heating, for if these are filled with water and this is permitted to freeze, bursting and dislocation often follow. The weight of fruit that Vines are capable of bearing depends entirely on their condition. We have seen some Vines more overloaded with a pound of fruit to every lineal foot of rod than others were with twice the weight of fruit. If each of your rods produce 18 lbs. of good well-finished Grapes you will not have much cause for complaint. The Grapes may hang on the Vines till after the leaves fall, provided the atmosphere of the house is favourable for the keeping of the fruit.

Propagating Hardy Ferns from Spores (T. H.).—Choose a pot which a bellglass will just fit within the rim, place a large crock over the hole, half fill the pot with smaller pieces, and on them place half an inch of moss; then fill the pot to the rim with the following mixture—viz., sandstone broken in all sizes from that of a grain to a hazel nut, sandy fibrous peat and yellow fibrous loam, of each equal parts, adding to the whole one-sixth of silver sand. Put over the surface a very small quantity of sifted soil, and make it firm by pressing it with the hand. Put on the bellglass, and if it fits closely on the soil it is all right. Remove it, and stand the pot in a pan in a rather shady but not dark part of the greenhouse, for what is wanted is a diffused though not a strong light. Give a good watering all over the surface through a fine-rosed watering pot, filling the pan with water. Now take the frond with the spore cases open, and, holding it over the pot, rub it with the hand on the under side, and a kind of brown or yellow dust will fall on the soil. You may scrape the spore cases from the back of the fronds, but if the dust fall so as to make the soil brown or yellow it is enough. Press the surface gently with the hand and put on the bellglass, taking care that it touch the surface all round. Keep the pan or saucer full of water, and give none on the surface except it become dry, which it never ought to do, nor will it if sufficiently shaded and the saucer be kept full of water. When the surface becomes green tilt the bellglass a little on one side at night, and as the soil becomes greener tilt it higher, giving a gentle watering now and then to keep the surface from becoming dry. When the plants have made two or three fronds gradually remove the bellglass, and pot off the Ferns when they can be handled safely. The pots may be placed in a pit or a shaded position in a greenhouse.

Potatoes in Pots (V. S.).—An excellent cultivator who successfully grows early Potatoes in pots, says:—"Ten-inch pots are the best, a hundred of these will give many dishes of fine early Potatoes, and when properly managed there is no risk with them. A crop may be relied on at all times with no more trouble nor expense than was required with the beds and frames. A quantity of roughish loamy soil should be collected, and a little decayed manure mixed with it. Each pot must have a little rough drainage placed at the bottom, and afterwards be half filled with the prepared soil. This should be made level and firm, and the sets can then be placed on it. Two, three, or four sets may be placed in each, keeping them as far apart as possible, and afterwards covering to the depth of 2 inches or more with the soil. A cool house or frame protected from frost are suitable places for the pots at first, as with a little water the sets will soon produce growths above the soil; and the cooler and nearer the glass the plants are kept at this period the more robust will they remain, and this is a great point gained. Later on they are placed in early vineries or Peach houses, and there the tubers form plentifully and swell quickly. As the weather becomes warmer, about the end of March and the beginning of April, they may be placed in frames with the lights over them. Where there is no room to grow many a few dishes may be had from one or two dozen pots, and when they are turned out we feel sure all will be satisfied with this easy and certain mode of securing Potatoes."

Culture of Oranges for Fruiting at Christmas (Excelsior).—The chief points that need attention are keeping the plants clean and not placing them in too large pots. The Orange, during the growing season, delights in an abundance of heat, light, and water; and secondly, it must be kept clean; and, thirdly, it should have a periodical rest. Of the first three essentials light is the most important. A deficiency of this is the source of more failures than is supposed, and too frequently the cause of failure is wrongly attributed to improper soil, too much or too little water, imperfect drainage, &c., although such may occasionally be the case. If we add to the first cause of failure an arid and sulphurous atmosphere, such as may be generated by flues and fireplaces underneath the structure, then ruin is the consequence. Light being a most important factor, let the trees be placed in such a position that the rays strike directly upon the upper surface of the leaves and all around the plant. Do not put them in the customary "shady corner," or the leaves are sure to fall prematurely; further, do not shade them from the sun unless they are either very sickly or in great danger of being scorched or burned, which is not likely to occur unless the glass is of inferior quality. Water ranks next in importance, as if the soil is tolerably open in character abundant supplies will be required from April to October, after which time it must be applied with a more sparing hand, the soil being allowed to become dry, but not dust dry, before it is applied. If drought is carried to extremes during the winter months the trees cast their leaves prematurely, thus weakening the trees considerably. The Orange being an evergreen, leaves should remain on the trees at least two seasons. In one of the most noted gardens in the kingdom this drying-off process was at one time carried so much to the extreme that when the plants were placed in their growing quarters in the month of April they resembled deciduous trees, and the flowers were consequently very scanty and fruits few.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (H. C.).—The Apple is one of the Calvilles, the fruits of which vary in colour according to soils and positions. The specimens bear a general resemblance to the Calville St. Sauveur, the fruits of which often keep till spring. Possibly it may be a local seedling, which would account for the variation from the original.

Names of Plants.—We only undertake to name species of plants; not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes, slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. —(G. M.).—*Bryophyllum calycinum*. (G. T.).—1, *Cypripedium Spicerianum*; 2, *Cymbidium eburneum*; 3, *Cattleya Trianae*. (R. O.).—1, *Cyclamen Coum*; 2, *Iris reticulata*; 3, *Azalea obtusa*. (W. G. S.).—2, *Adiantum pedatum*; 4, *Asplenium Adiantum nigrum*; 5, *Nephrolepis tuberosa*; 6, *Acacia Farnesiana*. The two Ferns (Nos. 1 and 3) cannot be recognised without spores. (F. M.).—The specimen was not in the best condition, but it appears to be a small flower of *Mackaya bella*. The plant will succeed best in an intermediate house, a cool stove, or a warm greenhouse, but not in an ordinary greenhouse. It can be grown in a pot or planted out, the soil consisting of turfy loam, with sand and a little peat or leaf soil. When the plant is growing weak liquid manure will be beneficial. (W. J.).—No numbers were attached to the specimens, so we can only give the names with the chance that you may recognise the plants to which they belong. *Cyrtomium falcatum*, bright shining green fronds; *Nephrolepis tuberosa*, frond with short sessile pinnæ; *Pteris serrulata*, frond with long narrow pinnæ.

VERMIN.

AN outcry about a plague of rats in Suffolk and certain other counties has led to much newspaper correspondence as to the reason why such vast numbers of this mischievous rodent have made their appearance in particular localities, and it has been insisted upon with persistent vehemence by certain writers that the whole and sole cause is excessive game preservation. Others deny that it is, and among them is a certain worthy farmer and land agent who cites, by way of example, his own case, where some 600 rats were destroyed recently, when a barn head was cleared of some old beans, which had remained there unthrashed since the harvest of 1888. He denies that game preservation is the cause, as it is not carried to an excess in the neighbourhood of his farm, and yet, strange to say, he does not appear to see that rat preservation is the cause.

What else can we call it when such ample provision of food and

shelter is made for them, and they are not only left undisturbed for more than twelve months, but no attempt appears to have been made to destroy them by poison? Yet their presence among the Beans in considerable numbers must have been palpable enough. If instead of rat preservation we take the more comprehensive and forcible term of slovenly farming, we shall have given the precise cause of the evil, and the remedy will be equally apparent. While walking over one of our off-hand farms last spring our attention was called to a beaten track made by rats across a field sown with spring corn to a stream, where they evidently came regularly in considerable numbers for water. The pasture on the other side of the stream rendered it more difficult to detect any track thence to the homestead, but we had lamentable evidence that the rats did cross the stream in our heavy losses from the broods of spring chickens. Now these rats came from some corn stacks on a neighbouring farm, so that our own pains in having rats kept under was thus rendered practically useless by the carelessness of a neighbour. Unfortunately he holds several thousand acres of land. He always keeps several old corn stacks unthrashed far into the new year, and we invariably see them so standing honeycombed by rats, with the earth burrowed around the foot of the stacks, and numerous holes made through the thatch. The case is undoubtedly a remarkable one, but actual observation for several years enables us to vouch for the accuracy of our statement, and to show how the careless suicidal habits of a single farmer may prove a curse to an entire district, and not merely a single parish, for his land runs consecutively through three or four parishes. It is notorious that rats are migratory, and with such a nursery for them can it be wondered at if they spread far and wide in ever increasing numbers?

If only every farmer would destroy rats systematically there would be no difficulty about keeping them under, and there can be no better time than this month and the next for the judicious use of poison for this purpose, so as to destroy as many old rats as possible before the spring litters make their appearance. The best way of doing this is to mix one part of meal with half a part of finely powdered loaf sugar, and one-eighth part of arsenic. Place the sweetened meal without the arsenic in the holes for two or three nights, and then use the poisoned meal. By this plan a clean sweep is made for the time of every rat on the farm, and mice may be kept down by placing the poisoned meal in the lofts and other places, where it is well out of reach of farm animals. For a small homestead a few slices of bread and fat, such as dripping or lard, covered with a thin coat of phosphorus paste placed near their haunts and well out of the way of other animals is an inexpensive and sure destroyer of both these pests. A regular old-fashioned rat hunt may be very good fun, but it generally involves much opening of drains, destruction of woodwork, and general damage, that we altogether prefer the poison as a preventive.

That prevention is better than cure certainly holds good in reference to vermin, for then we avoid the loss involved by their ravages. If the last sentence seems a mere platitude, why then, we ask, do farmers allow rats to become rampant? Why do they compare notes as to the number of bushels of Wheat per acre eaten by sparrows as the corn ripens, and yet suffer the "cloud" of sparrows which haunts every homestead in winter to remain unmolested? If the recent statement of a North Essex farmer in *Bells' Weekly Messenger* that sparrows destroy 8 bushels an acre of Wheat and Barley be true the loss is more serious than we supposed, for it amounts to a sum that would more than cover rent, tithes, and taxes.

WORK ON THE HOME FARM.

Management always tells, and never more so than in such a winter as the present one, when manure carting has been so much retarded by wet weather, and late ploughing of heavy land has spoilt it for Barley sowing. Repeatedly have we advised caution about ploughing such land when sodden with moisture, but then to those men who are always in arrears with their work advice of any sort is useless. With root land ridged in autumn we are now able to take full advantage of the drying

of the surface by the east wind and bright weather, to cart manure direct from the yards into the furrows, to spread it at once, and then split the ridges back over it with the double-breasted plough. There it is so left ready for the Mangold sowing in April, when manure carting would prove a serious hindrance to work generally. This advantage is a result of timely autumn culture, of a settlement of the next year's cropping at Michaelmas, and not waiting till spring before our plans for the year are matured.

To those who are in difficulties about heavy land Barley sowing we say, Don't sow Barley at all, but rather sow the best sample of Oats, either white or black. If the land is poor drill a full quantity of chemical manure with the corn, according to the formula we gave recently, and you will certainly have a profitable crop of corn, much more so than you would have by again trying to grow Barley on such land. Do not be bound by custom in a matter of such vital importance, but just consider the present price of English Oats, now 19s. to 26s. per quarter, compared with foreign Oats at 17s. to 22s. per quarter. Under high cultivation ten quarters per acre may be had of this crop. Can you do better with Barley? Can you do so well? And remember that Oats do not suffer from discolouration, that the straw is most nutritious for fodder, and that the crop is altogether less speculative in character than any other corn. Corn merchants turn to account the wretched light samples of foreign corn by offering "fine old English Oats" at special prices, just as a wine merchant puffs his fine old port. Winter corn generally is a full strong plant, but we hear of a few fields which have lost plants, and where this is the case we always drill Oats, such mixed corn always being turned to account for home consumption.

ENSILAGE.

ACTING on hints in your "Home Farm" columns, I ensilaged 7 acres of aftermath last autumn. The grass was stacked and bricks used for weight. The stack is now being cut, and has turned out in fine condition, so much so that it should stand a fair chance of a prize at any show. Could you please tell me whether there will be competitions at Smithfield or elsewhere during the next few weeks? My cows have taken to it at once.—A. W. G.

[If prizes are given for silage at the Horse Show, which opens at the Agricultural Hall, Islington, on March 4th, we fear you will find the list of entries is closed. Write to the Secretary, J. Herbert Taylor, 5, Great George Street, Westminster, S.W. You might also be able to compete at the Shorthorn Show at Bingley Hall, Birmingham, on March 5th, of which J. B. Lythall is Secretary; or at the Herefordshire Horse Show, at Hereford, on March 12th. The Secretary is W. T. Williams, 6, St. John Street, Hereford. But you would probably do better to hold some in reserve for the Spring Dairy Show, which will probably be held in London. Of this we are not certain, but a dairy show is clearly the best place for a silage competition. You are to be congratulated upon your enterprise and success in thus turning autumn herbage to account for a supply of prime winter food. The value of such an addition to our ordinary supplies of winter food for cattle is perhaps not so apparent just now, while hay is so cheap and roots so abundant; but it is nevertheless self-evident that such sound, wholesome, nutritious food, which can be had by most farmers at a nominal cost for collection and storage, and upon which no special outlay is required for cultivation, must come into general use. Ensilage is of especial value for your district, for Wales, for Ireland, and for every locality with a high average rainfall. In outlying districts, both in Ireland and Scotland, haymaking of a most primitive description may still be met with, much hay being spoilt, and much labour wasted, all which might be avoided by the substitution of ensilage for haymaking. and the exhibition of samples of well-made silage, everywhere and upon every opportunity, is so desirable that your desire to assist in so good a cause is highly commendable.]

REMARKS.

9th.—Fine, with occasional sun-hine.
 10th.—Sun shining through haze all day.
 11th.—Bright and cold.
 12th.—Bright and cold.
 13th.—Sun shining through haze in morning; bright afternoon.
 14th.—Cloudy morning; dull, with occasional slight drizzle in afternoon.
 15th.—Wet snow early, (covering the ground about an inch deep by 9 A.M.) turning to rain about 10 A.M. and lasting all day.
 Early part of week very bright and fine, latter part snowy and wet.—G. J. SYMONS.

PLANT TOPICS.

—+—

REMARKABLE plants have received a large share of attention lately, both in the horticultural and daily press; writers in some of the leading metropolitan organs devoting exhaustive, poetical, and imaginary articles to subjects that have been brought into prominent notice for some peculiar character. Few plants can claim the honour of having a whole scientific report devoted to them, yet this has been accorded to "the Weather Plant," concerning which notices have appeared in numberless papers, both here and on the continent. As *Abrus precatorius* this plant had long been a familiar occupant of botanic gardens, and its brilliant red black-tipped seeds are frequently seen in museums, either preserved as curiosities or employed in ornamental articles of native manufacture. An observer on the continent some time since, however, detected certain movements of the leaves that appeared to be connected with meteorological disturbances or changes, and the attention of scientific men was especially directed to it. An important ultimate result of this was the institution at Kew of a series of experiments, intended to test the reliability of the *Abrus* as a natural meteorologist and prognosticator of the weather. It must here be noted that the plant is a native of the West Indies, and though it succeeds in other tropical countries it was a severe test to expect it to act as a faithful indicator of the varying weather conditions of this climate. Possibly this may have disturbed the sensitive constitution of the plant sufficiently to account for the erratic nature of the record obtained, for though it was satisfactorily proved that the weather influences the movement of the leaves to a certain extent, yet it does not appear that any definite rules can be laid down as to its behaviour. The prognostications of the meteorological office have frequently been the subject of satirical comments, but those of the *Abrus* are certainly less reliable, as far as can be judged from the admirable report so carefully prepared by Mr. Francis Oliver.

The responsive action of plants, more particularly the leaves and flowers, to changes in the weather is not peculiar to one or two members of the vegetable kingdom, it is shared in some degree by a large number. Some of our most common wild plants are influenced considerably by light, heat, damp, and cold in the movements of their leaves. What is termed "the sleep of plants" is merely an effect due to the withdrawal of light or heat. Many observers have called attention to this, and to the varying mode in which the leaves fold up or are depressed in different species. It is more notable in compound leaves than in simple ones, and the position assumed by the leaflets in the Trefoils is familiar to everyone, each one folding on itself, and then the three draw up to the axis, being nearly upright. In species of *Oxalis* with similarly formed leaves, the leaflets droop downwards round the stalk. In pinnate leaves the pinnæ are often depressed below the stalk, the under surfaces meeting.

Flowers commonly expand in the morning and close in the evening, frequently remaining closed in dull, cold or wet weather. All such movements may therefore be considered as due to meteorological influences, though they have never yet been reduced to a system. It is true that with regard to the times at which flowers expand and close a kind of floral clock has been composed, but the times given for the various flowers can only be taken as approximative, and the divergence of an hour or two rather dis-

turbs the calculation of time by such means. All movements of plants in this way seem to depend upon so many conditions which are difficult to ascertain and cannot be accurately recorded, that it is too much to expect really definite results.

Spontaneous movements of leaves, or those in response to some direct irritation, are more interesting and more regular. They have been subjected to close scientific study in the case of such as the *Dionæa* and *Droseras* with surprising results, the carnivorous plants having enjoyed a notoriety far exceeding the "Weather Plant." Even now they are inquired for by visitors to Kew with somewhat the same impressive interest that the lion house is sought in the Zoological Gardens. The infolding of the leaf lobes in the *Dionæa* when some substance is introduced is familiar to many now, as also is the rapid drooping of the Sensitive Plant leaves when touched. There is, however, an occupant of the stoves in some botanic gardens which displays a still more remarkable phenomenon in its leaves, and which is not nearly so well known. This is the Telegraph Plant, *Desmodium gyrans*, a member of the Leguminosæ, a native of the East Indies, and by no means a novelty. Though Mr. Darwin and others have determined that most plants have a spontaneous motion in their growing stems and roots, these are so extremely gradual that they are not readily observed, and can only be tested by careful experiment. In the *Desmodium*, however, we have a spontaneous movement that is visible and strongly marked. The leaves consist of three leaflets, the centre one large, oblong, or elliptical, and at the base on each side is a small narrow leaflet, which possesses a peculiar property. When the plant is healthy and growing these leaflets rise alternately by a series of little jerks until they are nearly perpendicular, and then descend in a similar way, to resume their action when the other leaflet has gone through a similar process. This takes place without the application of any external stimulant beyond that afforded by light or heat; the rapidity of the movement varies greatly, however, and in dull weather it is much reduced or ceases altogether, as it does when the plant becomes unhealthy or old. Sometimes the motion is confined to a few leaves, but it seems to depend chiefly on the age of the plant, the weather, or the conditions under which it is grown. In cold or a dry house it is much lessened, and does not continue so long.

As regards the benefit plants themselves derive from these movements it is easy to understand that in the case of leaves folding up in dull weather or at night, the radiating surface is decreased. Flowers are also protected by closing in cold or wet weather. The *Dionæa* and others having a similar character are believed to derive nitrogenous support from the flies and other insects they entrap. What advantage, however, can the Sensitive Mimosa or the Telegraph Plant derive from the motion of their leaves? In a wild state we could imagine that the Mimosa is subject to a perpetual succession of alarms, and how can the drooping of its leaves protect or help it? The restless action of the *Desmodium* leaflets might serve as an attraction, but if so it expends a considerable amount of energy in accomplishing what many other plants effect by means of their flowers in a quiet but much more certain manner.

Another plant topic which has been treated rather fully, popularly, and practically in the papers lately is in connection with fragrant Ferns. Mr. W. Sowerby recently called attention to the fact that the fronds of *Drynaria Willdenovi* possess an agreeable haylike fragrance when drying, and immediately the writers were busy in the daily Press extolling its virtues and enlarging upon the subject generally. It is rather strange that this quality of the *Drynaria* (or *Polypodium* as it is designated in the "Synopsis Filicum") has not been recorded before, but fragrance is not expected in Ferns, and it is only those who are intimately acquainted with them that would be likely to detect their peculiarities in this respect. Still, there are several Ferns which possess an un-

questionable fragrance in their fronds, surpassing both in quality and degree that of the *Drynaria*. *Lastrea* or *Nephrodium fragrans* (noted on page 175) is one of the most remarkable of these, and it was the first "Fragrant Fern" that I knew. Some years ago an experienced Fern grower in the north of England called my attention to its Violet-like odour, and at the time I thought it was a practical joke, so strong was the fragrance, it seemed scarcely credible a Fern could produce it. Two British Ferns, *Nephrodium æmulum* and *N. montanum*, also possess a marked fragrance in their fronds, the former partaking of the fresh hay character distinguishing the *Drynaria*. Some other Polypodioids have been observed that are entitled to rank with "Fragrant Ferns," such as *P. normale* and *P. phymatodes*, but in few is it so distinct as in *N. fragrans*.

A considerable difference of opinion exists respecting the assistance a gardener can derive from a knowledge of the conditions under which a plant flourishes in its native state. It is contended that under cultivation plants are necessarily treated so artificially that it is practically impossible to reproduce exactly what they are supposed to require. Further, it is maintained that plants are often found growing in places that are not best suited for them, but which they are forced to occupy by being "crowded out" in the "struggle for existence." Much of this is undoubtedly true, but it is also equally the fact that a knowledge of the habitat of a newly introduced plant is a considerable help to a cultivator, and many who have to deal with such could testify to the correctness of this view. It is frequently deplored that collectors furnish too little information on this score, though they could always do so without revealing any trade secrets with regard to the localities where scarce or valuable plants are found. A man may possibly succeed in growing a plant well though he has no knowledge of its native climate or surroundings, but he is much more likely to do so if he be in possession of a few facts. The innumerable failures with Orchids when they were first cultivated were unquestionably due to the fact that the treatment was founded on imperfect knowledge. Modifications have to be introduced in all cultural matters in accordance with the conveniences at command, but a general idea of the plant's requirements is a useful guide in experimental culture.—L. C.

TOMATO DISEASES, CAUSES AND PREVENTION.

THE roots of Tomato plants, under certain conditions, become in some cases almost covered with tuber-like knobs similar to those on the roots of Cucumbers. At one time I regarded this to be the work of an insect, but by careful observation, and noting the conditions under which it has appeared, have been compelled to draw other conclusions. Old soil, or soil that has been used for the same crop, has been carefully avoided, but this did not prove sufficient. Then the use of fresh manure was discontinued, but this it was found was not the cause, although it may be pointed out that fresh manure is the reverse of beneficial to these plants. Where this clubbed appearance of the roots takes place with us the strictest measures were taken to prevent it, but with no avail. The disease appeared in one bed only, two other narrow borders being occupied with Tomatoes in the same house. Tomatoes were also grown in four or five other positions, with no sign of clubbing. Ultimately I came to the conclusion that the disease is mainly, if not wholly, due to a superabundance of bottom heat. I am also of opinion that the clubbing of the roots of Cucumbers is due to the same cause. None of the plants in the various houses had bottom heat, except in this one place where clubbing occurred. The bottom heat pipes were shut off under the two beds, which were formerly used for early Melons and propagating. At the back where the roots clubbed the top heat pipe was shut off, but the heat, backed up from the return and the pipe, was frequently very hot—too hot for the well-being of the plants—and resulted in the disease that has been pointed out.

Place these plants in loose rich soil, or soil in which too much manure has been incorporated, so as to cause a soft sappy growth, and maintain a humid atmosphere for forty-eight hours, and the plants are attacked by *Phytophthora* (*Peronospora*) *infestans*. When the soil is firm and not too rich this fungus will appear if

the temperature is low and the atmosphere becomes saturated, or nearly so, even for a very short time. This is not the only cause, and another may be pointed out. How often are the plants divested of a good portion of their foliage and then given a soaking of water. We have been guilty of this, and know that it is practised by many others. No greater mistake can be made, for it is almost certain to predispose robust plants to this disease. They are attacked in such a short time that the main cause may for a long time be overlooked. After thoroughly watering a house of Tomatoes the atmosphere for a time is often too moist, and if a good percentage of foliage has been removed it adds to the evil. If the borders in which they are growing have been dry the evil is increased. No fear of an attack from fungus need be anticipated if the temperature of the house is slightly increased for a time after watering, so as to assist in evaporating the superfluous moisture. If the weather is warm and bright, this can be accomplished by ventilating on a more liberal scale, and watering during the early part of the day. The plants should be dressed two or three days previous to watering, or about the same time afterwards. This disease can be prevented by warmth, the atmosphere on the dry side, and judicious ventilation, combined with careful watering, and soil that will promote firm sturdy growth.

When once the disease appears it can be stopped, and must be at once, for it soon communicates itself to healthy plants if the treatment is not changed and a remedy applied at once. It is surprising how quickly the whole tissues of the plant become diseased, and once it reaches this stage all remedies are hopeless, nothing remains but to burn the plants. They never do any good, all new growth becomes diseased just when hopes are entertained of the plant recovering. The moment it shows itself all infested leaves and any portions of the stems should be cut away at once and burnt, and the plants syringed with powdered sulphur and water. For this purpose a 4-inch potful of sulphur will be ample for three or four gallons of water. This will destroy the fungus and save the whole house of plants if other conditions are at once rendered favourable. Neglect for a few days may result in all the plants having to be destroyed.

Another and certain cause of this disease is excessive watering, which is easily remedied by care. It promotes soft growth, bad setting, and in the end disease. If Tomatoes are properly managed they do not require half the water that some think necessary for their well-being. The less they have to be watered, as a rule, the better they succeed. In some positions and under certain conditions during hot dry weather the plants may have to be watered daily to keep them from suffering by drought. Where the conditions of the roots are such that this has to be done to maintain moisture about them, the best interests of the plants are sacrificed. The soil in which they are growing should never be destitute of moisture from the time they are started until the whole of the crop has been gathered. If kept as near an intermediate condition as possible so much the better without recourse to frequently watering them. They do not need much soil in which to grow, and if the surface is thoroughly mulched to prevent evaporation the plants will do all the better, and the roots continue to work freely from first to last. If grown in pots the advantage is on the side of plunging; they require less water, and in consequence afford a heavier crop of fine fruit. The plants that had the least water with us last year were the best, and the same fact was observable under the various conditions under which others were grown.

There is another fungus that attacks these plants, and which is encouraged by a low stagnant atmosphere. Ten days or a fortnight is ample under certain conditions of culture for a whole house to be covered—leaves, stems, and fruit—with a brown mould. This gives to the foliage a dried up appearance, as if they were ripening prematurely. This is bad if allowed to spread unchecked, and will soon ruin the crop. But it is not such a serious disease as the former, that blotches the fruit, leaves, and stems at first as if they had been scorched. Directly this is observed the plants should be thoroughly syringed with the sulphur solution that has been pointed out, and the temperature slightly raised where this is practicable, and it will be destroyed in a few days.

All that is needed to guard against these diseases is a moderately warm rather dry atmosphere. A liberal circulation of air on all favourable occasions promotes firm sturdy growth. This is essential to success. Early Tomatoes, after they commence growing freely, are often kept too warm and too close, and are given twice the quantity of water that they really need.

The soil must be firm and not too rich, the growth of moderate strength—that is, firm and short-jointed. Loose rich soil promotes undue luxuriance. It is possible to have the plants too strong to ensure their setting freely, even if such sappy examples of growth do not fall an early prey to disease. On the other hand

the plants should not be starved, so that they grow only with difficulty and produce three or four puny flowers on each truss.—WM. BARDNEY.

THE BRUSSELS SPROUT.

THERE is scarcely another vegetable with which we have to do that is of greater importance considered as a kitchen garden crop than this one, and perhaps, with the exception of Peas, no other vegetable has had more time and thought devoted to its improvement within the last few years.

This extra attention has resulted in producing hybrids and varieties in great numbers, all of them claiming to be improvements in one way or the other over the old Brussels Sprout. Novelty and variety have charms which are irresistible to most people, and I am afraid that very few have resisted its influence with this vegetable but have sought for the new and sacrificed the old. All honour to those who are endeavouring to improve this important vegetable, and I hope that success may crown their efforts, but up to now, in my opinion, it has entirely eluded their grasp.

In size of stem and also of the sprout, improvement no doubt has been effected, but I believe at a great sacrifice in other important respects, the chief of which is in quality, weight, and economy.

In determining the relative value, or quality, as between the small, hard, knotty sprout of a few years ago against the loose and large sprout of the present time, apart altogether from my opinion on the subject, let anyone inquire of their cooks which are preferred at table, or of the salesmen which are preferred at market. As regards value or weight from a given quantity of ground I hold that the small sprout has also the advantage.

In planting ground with the Improved or, as they are sometimes called, the Giant Sprout, it is advised that they be planted 3 feet apart, and sound advice too, as the plants will meet even planted at this distance apart before the winter. They have stems and leaves like Castor-oil Plants, and almost as ornamental, but unfortunately these stems and leaves are fit only to be eaten by pigs or cattle. The sprouts are usually large and loose, and when once in the kitchen half the outer leaves are stripped off in being prepared for cooking, and it frequently happens that many of the largest sprouts are diseased in the centre, and therefore useless.

The smaller Brussels Sprout may be planted from 18 inches to 2 feet apart each way, according to the richness or otherwise of the ground, thus giving double the number of plants to the same area, and nothing like the weight of useless leaves and stems, and a much greater weight of serviceable sprouts of far better quality and with scarcely any waste in preparing for cooking.—OWEN THOMAS, *Chatsworth*.

SOME EARLY CROCUSES.

WHILE the large Dutch Crocuses are ever welcome in their season, there are many species of the genus which flower earlier and gladden our eyes with their brightness. True harbingers of spring, heralding its approach, and with it the glowing masses of golden yellow, or the purples and lilacs and whites of their larger congeners. These winter Crocuses begin early in the year, opening their blossoms with the first gleams of sunshine which peer through the gloom of our early January days. Some of these Crocuses appear to have greatly exercised the reporters of some of the daily journals at the recent meeting of the Royal Horticultural Society, and one of these seemed to suspect that the specimens exhibited by a well-known firm had undergone some mysterious operation to induce them to flower at such an early season.

As yet I cannot boast of the possession of a large number of these; but year by year some are added, and others increase in number, so that I look forward hopefully to the possession of large clumps of the winter flowering species. It is fortunate that some of the best of these early Crocuses are moderate in price, so that the amateur who has to study economy, and the gardener who requires to be careful in his expenditure to avoid involving his employer in a heavy bill, need not be without some of these charming little flowers, which peep brightly from the earth when all around is dull and dreary. The present notes have no pretension to being exhaustive of the many species, but are penned with the view of drawing more attention to the claims of some of the cheaper species which may be purchased in quantity.

My first acquisition among these was *C. Imperati*, which I have previously mentioned in these pages, and which, although comparatively common, is still absent from the vast majority of gardens. Few are more beautiful to the admirer of the genus, with its delicate fawn coloured outer petals beautifully pencilled with dark

purple, so dark as to be not far from truthfully called black by many. Thus when in bud the flowers exhibit a delicacy and refinement which charm the careful observer, but when the flowers open the expanded petals are of a beautiful violet or purple. There is also a white variety which is still high in price, and another new form named *C. Imperati longiflorus*. Another neat little Crocus, apparently closely allied to *C. Imperati*, is *C. minimus*. This is inferior in beauty to the former, the colours and pencilling being less distinct.

Another very pretty little winter flowering Crocus is *C. Aucheri*, a Greek species, which is well figured in Wooster's "Alpine Plants." The flowers are small but freely produced, and are of a beautiful orange with a blackish stain at the base of the petals. This species possesses one advantage over *C. Imperati* in being as bright when in bud as when expanded, an advantage not to be under-estimated, as it must be remembered that sunny days are none too plentiful in January in our northern clime. *C. Aucheri* is said to be synonymous with *C. Olivieri*, but, unless I am mistaken, the latter is commoner and cheaper, being known to the Dutch by the name of *Botergeel* (butter yellow). I am not so fortunate, however, as to possess Mr. Maw's monograph of the genus, the recognised authority as to the various species.

Another beautiful species possessing the advantage of brilliant outer petals is *C. Sieberi*, which forms a fine companion to *C. Aucheri*. The flowers of this are usually described as pale purple, a description which, while possibly correct from a colourist's point of view, deprives the mind of the reader of a realisation of the brightness of the flower. This is a bright little species, and was in bud with me on New Year's Day, and is still in flower. *C. Sieberi* has a yellow zone inside, and is marked with deep yellow stains at the base of the outside of the petals. This is also a native of Greece.

A species which is so cheap that it may be deemed almost unworthy of special note, costing little more than the Dutch Crocuses, is *C. biflorus*, known as the Scotch Crocus—why I know not, as, so far as I am aware, it is not a native of Scotland. This species in time of flowering links together the early and the later Crocuses. The type is white outside, assuming a purplish tinge with age, and feathered with deep purple. When expanded the flowers are pure white with a bright yellow zone. *C. biflorus* is a special favourite with the bees, which seem to prefer it to any others. It has a distinct sweet perfume, which may possibly attract them. I have often watched them as they hummed about and extracted the nectar from a large clump which delighted me with its beauty.

Some other species and varieties might have been named, but I fear these notes have already extended to an undue length, and they must be reserved for some other time. There is no need to give details as to their cultivation. A sunny sheltered position should be chosen for them, and a sheet of glass or a handlight placed over them in stormy weather will give all the protection these charming flowers require to enable them to open their beautiful blooms, and reward their possessor for his little care and expense.—S. ARNOTT.

THE NATIONAL CHRYSANTHEMUM SOCIETY.

WE learn that in view of the Centenary Festival of the above Society, the list of Vice-Presidents is being extended, and donations are flowing in to Mr. Holmes at quite an overwhelming rate. Amongst the latest additions to the dignitaries named, are the Duke of Westminster and the Right Hon. J. Chamberlain, M.P. Several fresh societies have also become affiliated. Matters generally, indeed, seem to have a roseate tint.

CHRYSANTHEMUM ANALYSIS, 1885-1889.

THE last November Show of the National Chrysanthemum Society was the smallest they have yet held. The fixture was well timed for anything like an average year, but the flowering season of 1889 proved so remarkably forward that a very large number of the best flowers were over in many localities before this Exhibition came on. For our present purpose this may be regarded as rather a fortunate circumstance than otherwise. The fact is the early varieties having been in recent years unduly favoured by the seasons now stand somewhat higher, and the later sorts somewhat lower in the analysis than they are justly entitled to do; it is therefore only right and fair that on this occasion the late-flowering varieties should have had a little extra consideration shown them. The following short table shows the total number of incurved

and Japanese Chrysanthemums staged in competition at all the leading exhibitions held by the National Society up to the present time :—

1885	Incurved	839	Japanese	835
1886	"	1080	"	1026
1887	"	964	"	1221
1888	"	1147	"	1759
1889	"	682	"	922
		4712		5763

It will thus be seen that about 10,500 blooms have been tabulated in all; the outcome of which tabulation will be found in the accompanying tables of the Incurved and Japanese sections.

As in former years the established varieties are arranged in the tables according to the average number of times they were shown at all the five Exhibitions. In the case, however, of the newer sorts a rather different system has to be adopted, as Chrysanthemums are not as a rule in the hands of exhibitors generally for the first year or two after they are distributed. Accordingly those varieties which came out in 1886 are allotted places according to the frequency with which they were shown at the last two Exhibitions of the Society, while the positions accorded to the still newer kinds—those of 1887, 1888, and 1889—are entirely dependent upon the number of times they were staged at the Royal Aquarium in November last.

Taking first the table of Incurved varieties, we still find Empress of India, immediately followed by Queen of England, at the head of the analysis, and yet the first named is the oldest but five, and the other the oldest of all on the list. The sorts which stand out as having been more frequently shown than usual are Alfred Salter, Emily Dale, Princess of Teck, Cherub, Empress Eugénie, Mr. Brunlees, and notably Barbara,

which has risen three steps since last year. On the other hand Jeanne d'Arc, Lord Wolseley, Mr. Bunn, Nil Desperandum, Jardin des Plantes, and Prince of Wales were very indifferently represented.

Neither of the two 1886 varieties have improved their positions since the last list was issued; indeed, Bronze Queen of England has fallen from No. 22 to No. 30, while Mrs. Norman Davis, although a late sort, still remains at the bottom of the analysis. It is, however, pleasant to welcome two new kinds, which have already on their first appearance so greatly distinguished themselves as have Miss M. A. Haggas and Violet Tomlin. The former has at once risen to No. 22, and the latter to No. 24 on the list. Both of these were sent out in 1888. The only new Incurved varieties which appear in the present analysis, and are not to be found in the first one published five years ago, are these same four varieties—viz., Miss M. A. Haggas, Violet Tomlin, Bronze Queen of England, and Mrs. Norman Davis, showing what little progress has been made in this section in recent years.

Of all the Japanese Chrysanthemums the one which was most frequently shown last year was Edwin Molyneux—nevertheless, the blooms of this fine new variety were, as a rule, inferior to those staged at the previous Exhibition. Madame John Laing was to be seen in nearly as many stands as Edwin Molyneux, and was moreover splendidly represented. Other sorts specially favoured by the season were Val d'Andorre, Mr. Ralph Brocklebank, Carew Underwood, Meg Merrilies, Boule d'Or, Baronne de Prailly, Japonais, and Gloriosum; and yet only four of these ten Japs are classed in the National Chrysanthemum Society's catalogue as late-flowering kinds. The following, together with many other well-known sorts, were, on the other hand, scarcely anywhere to be seen :—Maiden's Blush, Comte de Germiny, La Triomphante, Bertier Rendatler, Monsieur Astorg, Peter the Great, and Monsieur Tarin.

INCURVED VARIETIES.

Position in Present Analysis.	Average Number of Times Shown in the Five Years.	Number of Times Shown in 1889.	Name.	Date of Introduction.	Raiser's or Introducer's Name.	Colour.
1	58·4	48	Empress of India	1861	{ Downie, Laird, and Laing	Pure white.
2	52·8	49	Queen of England	1847	J. Salter	Delicate rose blush.
3	48·8	42	Lord Alcester	1882	Freemantle	Pale primrose.
4	47·0	43	Golden Empress of India	1877	Loader	Pale yellow.
5	43·4	30	Jeanne d'Arc.....	1881	Lacroix	Blush white, tipped purple.
6	37·4	22	Lord Wolseley	1883	Orchard	Bronzy red.
7	37·0	26	John Salter	1866	J. Salter	Cinnamon, orange centre.
8	33·2	21	Prince Alfred	1863	Davis	Rose carmine, shaded purple.
9	32·6	26	Alfred Salter.....	1856	J. Salter	Clear lilac pink.
10	31·8	22	Princess of Wales.....	1865	Davis	Blush, tinted rose.
11	31·6	11	Mr. Bunn	1881	Bunn	Bright golden yellow.
12	30·2	31	{ Emily Dale	1874	Dale	Pale straw colour.
			{ Golden Queen of England	1859	J. Salter }	
13	28·2	10	Nil Desperandum	1862	Smith	Dark orange red.
14	24·6	15	Lady Hardinge	1861	Clark	Silvery rose.
15	23·4	13	Jardin des Plantes	1859	J. Salter	Deep golden yellow.
16	20·8	27	Barbara	1869	J. Salter	Bright amber, shaded orange.
16	20·8	12	Mrs. W. Shipman.....	1878	Shipman.....	Fawn colour.
17	19·2	12	Mrs. Heale.....	1867	Heale	Pure white.
18	18·4	17	Princess of Teck	1868	Pethers	White, suffused pink.
19	17·6	13	Hero of Stoke Newington	1873	Forsyth	Rose pink.
20	16·4	1	Prince of Wales	1865	Davis	Purple.
21	16·2	11	Refulgens	1873	Cannell	Rich purple maroon.
22	16·0	16	Miss M. A. Haggas	1888	—	Soft bright yellow.
23	15·8	15	Cherub	1862	Smith	Orange, tinted rose bronze.
24	14·0	14	Violet Tomlin	1888	Doughty	Bright violet purple.
25	13·4	6	Venus.....	1863	J. Salter	Lilac, suffused pink.
26	12·6	4	Beverley.....	1863	Smith	Cream white.
26	12·6	2	White Venus	1872	Shrimpton	Pure white.
27	11·6	1	Golden George Glenny.....	1876	Dixon	Bright yellow.
28	11·4	15	Empress Eugénie.....	1866	Pethers	Rosy lilac.
29	11·2	14	Mr. Brunlees	1884	Smith	Indian red, tipped gold.
29	11·2	11	Princess Beatrice	1868	Wyness	Delicate rose pink.
30	10·0	4	Bronze Queen of England	1886	Carter	Bronze brown, tinted rose.
30	10·0	2	Mr. George Glenny	1870	Waters	Primrose yellow.
31	9·4	4	Mrs. George Rundle.....	1868	Rundle	Pure white.
32	8·0	5	Golden Eagle.....	1863	Davis	Reddish bronze, tipped orange.
33	6·8	5	Baron Beust	1868	Pethers	Chestnut red, shaded yellow.
34	6·4	1	Eve	1865	Smith	Cream white.
34	6·4	1	Lady Slade.....	1864	Smith	Lilac pink.
35	6·2	5	Mabel Ward	1882	Ward	Buff yellow.
36	5·5	6	Mrs. Norman Davis	1886	Mizen	Rich golden yellow.
37	5·2	3	Novelty	1860	Clark	Blush.

Of the 1886 flowers no fewer than find eleven places in the present analysis. At the head of these, at No. 4, stands Edwin Molyneux. Mr. Ralph Brocklebank (the pale yellow Meg Merrilies) comes next at No. 11, while a little lower down at No. 16 we come upon Carew Underwood—the beautiful bronze sport from Baronne de Prailly. Madame Baco (No. 43) and Monsieur Bernard (No. 51) have also risen

in the analysis, but Monsieur J. M. Pigny (No. 36), Mrs. J. Wright (No. 39), Florence Percy (No. 43), Roi des Japonais (No. 45), Monsieur H. Elliott (No. 49), and Amy Furze (No. 57) have all apparently declined in public favour. I say apparently, because in so abnormal a season anything like an early sort had but little chance of becoming fairly represented.

JAPANESE VARIETIES.

Position in Present Analysis.	Average Number of Times Shown in the Five Years.	Number of Times Shown in 1889.	Name.	Date of Introduction.	Raiser's or Introducer's Name.	Colour.
1	49.0	32	Madame C. Audiguier	1879	Marrouch	Deep mauve.
2	47.6	30	Mdlle. Lacroix	1880	Lacroix	White.
3	41.0	5	Maiden's Blush	1885	Stevens	Creamy white, tinted blush.
4	39.5	41	Edwin Molyneux	1886	Cannell	Chestnut crimson, golden reverse.
5	37.4	32	Jeanne Délaux	1882	Délaux	Dark crimson maroon.
6	36.4	31	Val d'Andorre	1883	Pertuzès	Orange red.
7	34.0	22	Fair Maid of Guernsey	1872	Downton	Pure white.
8	32.0	32	Avalanche	1887	Cannell	Snow white.

28	16.2	5	Mdlle. B. Pigny	1885	—	White.
29	15.2	12	L'Adorable	1885	Délaux	Canary yellow, tipped purple.
29	15.2	12	Triomphe de la Rue des Châlets	1881	Pertuzès	Reddish salmon.
30	14.4	4	Madame de Sévin	1884	—	Rosy purple.
31	13.6	13	Duchess of Albany	1883	Jackson	Orange buff.
32	13.4	1	Hiver Fleuri	1879	Délaux	Creamy white, suffused pale rose.
33	12.6	8	Monsieur J. Laing	1884	Délaux	Reddish brown, gold reverse.
34	11.6	0	Triomphe du Nord	1857	—	Bronze crimson.
35	11.4	9	Yellow Dragon	1863	Salter	Bright golden yellow.
36	11.0	21	Gloriosum	1885	Waterer	Orange to golden yellow.
36	11.0	8	Monsieur J. M. Pigny	1886	Audiguier	White.
37	10.8	3	Monsieur Ardène	1878	Lacroix	Rosy lilac.
37	10.8	6	Monsieur Freeman	1885	Délaux	Purplish rose, white centre.
38	10.6	3	Fernand Féral	1884	Délaux	Rosy mauve.
39	10.5	7	Mrs. J. Wright	1886	Laing	Pure white.
40	10.2	1	Album Plenum	—	—	Creamy white.
41	10.0	0	Flamme de Punch	1883	Délaux	Orange, shaded red.
42	9.4	5	Monsieur Brunet	1879	Lacroix	Lilac mauve.
43	9.0	4	Florence Percy	1886	Allen	Creamy white.
43	9.0	12	Madame Baco	1886	Davis	Deep rose.
44	8.6	7	Comtesse de Beauregard	1867	J. Salter	Rosy lilac.
45	8.5	5	Roi des Japonais	1886	Lacroix	Crimson maroon, tipped gold.
46	8.2	0	Margot	1883	Délaux	Rosy salmon.
46	8.2	1	Monsieur Délaux	1877	Délaux	Red crimson, yellow centre.
47	8.0	8	Condor	1888	Boucharlat	White.
48	7.6	3	Baltimore	1878	Délaux	Rosy purple.
48	7.6	0	Dr. Macary	1878	Délaux	Rose and white.
49	7.5	9	Monsieur H. Elliott	1886	Délaux	Salmon-buff, tinted rose.
50	7.2	1	Bouquet Fait	1880	Délaux	Soft rose pink.
50	7.2	0	William Robinson	1884	May	Orange, tinted rose.
51	7.0	1	Fanny Boucharlat	1879	Délaux	Creamy white.
51	7.0	11	Monsieur Bernard	1886	Laing	Rosy purple.
52	6.6	3	Dormillon	1883	Lacroix	Rose purple.
53	6.5	2	Martha Harding	1885	Stevens	Golden yellow, shaded orange.
54	6.4	0	Monsieur H. Jacotot	1883	Délaux	Rich crimson, shaded gold.
55	6.0	6	Etoile de Lyon	1888	Boucharlat	Rosy purple.
55	6.0	6	George Daniels	1888	Boucharlat	Pale pink.
56	5.8	4	Grandiflorum	1863	Fortune	Bright golden yellow.
57	5.5	5	Amy Furze	1886	Coombe	Blush rose, tinged lilac.
58	5.4	0	Source d'Or	1882	Délaux	Orange, gold shading.
59	5.2	0	Agréments de la Nature	1881	Délaux	Rich golden yellow.

Mr. Garner having retired from the list, it is to be hoped not permanently, we are indebted to the year 1887 for only one single Jap—Avalanche. This superb flower has, however, in this one year, and that by no means a favourable one for the variety, risen from No. 21 to No. 8 in the analysis. In fact in 1889 it was staged as often as the premier flower—Madame C. Audiguier.

Sunflower, another splendid novelty and the champion flower of 1888, on what is virtually its first appearance at once takes a prominent position, having been staged twenty-seven times last year and already standing No. 13 on the list. The rest of the new sorts sent out in the same year will be found as follows:—Condor at No. 47, and Etoile de Lyon and George Daniels both at No. 55. These latter are certainly modest positions, but then it must be borne in mind what youthful aspirants for fame these 1888 varieties are, and that it is not given to all good new varieties to take the Chrysanthemum public by storm as Edwin Molyneux, Avalanche, and Sunflower have done in recent years. I find that no fewer than twenty-four new Japanese Chrysanthemums appear in the analysis this year which were absent from that issued only five years ago. Among these may be mentioned Maiden's Blush, Edwin Molyneux, Avalanche, Madame J. Laing, Mr. R. Brocklebank, Sunflower, Carew Underwood and La Triomphante as undoubted acquisitions.

REFLEXED, LARGE ANEMONES, POMPONS, AND POMPON ANEMONE VARIETIES.

Judging by the number of times the different varieties were shown at the last few exhibitions of the National Chrysanthemum Society the following short lists represent the cream of the above sections.

Reflexed.—Cullingfordi, Cloth of Gold, King of Crimson, Golden Christine, Pink Christine, Chevalier Domage, Peach Christine, Phidias, and Dr. Sharpe.

Large Anemones.—Lady Margaret, Empress, Emperor, Acquisition, Gluck, Georges Sand, Fleur de Marie, Mrs. Pethers and J. Thorpe, junr.

Pompoms.—Black Douglas, Mdle. Marthe, Golden Mdle. Marthe, Mdle. Elise Dordan, Prince of Orange, Marabout, and President.

Pompon Anemones.—Antonius, Mr. Astie, Marguerite de Coi, Madame Chalonge, Miss Nightingale, Perle, Marie Stuart and Astrea.

I once more, in conclusion, express my indebtedness to Mr. Harman Payne for providing me with the dates and raisers' names of a few of the newer Japanese Chrysanthemums in the foregoing tables.—E. M., *Berkhamsted*.

PARSLEY.

SOME vegetables it is possible to dispense with should a failure occur, but as regards Parsley there is no cessation in the demand, and scarcity means worry at the very least. Then it is such a common everyday crop that very little it may be considered can be said about it. But experience has shown me that even with Parsley there is a right method of proceeding, and no doubt many wrong ways of treating it. In the first place I should say a good strain is of the first importance, and on that account for many years I have selected a few plants and procured seed from these. In a good strain the leaves should be light green in colour, of moderate growth, and the foliage well curled. Then a poor soil seems to be better than a rich one; indeed, dung should on no account be applied to ground on which it is intended to grow Parsley. Lastly, in order to make as sure as possible of a continuous supply two sowings should be made. Though I do not always practise this myself, yet the omission of the second sowing is risky. I need only enlarge somewhat on the sowing and treatment of the plants. Make the earliest sowing by the beginning of March, and select soil in good condition. By May the young plants will be large enough to be transplanted on a damp cloudy day. Set the plants in rows 12 inches apart. One watering at the time of planting is all that is required, the ground is hoed immediately after finishing, and an occasional hoeing is all the plant will require throughout the summer. Where a continued and unceasing supply has to be met a large number of plants must be grown, say from 500 to 1000. Each plant forms a large tuft of leaves, and the large quantity does away with the necessity of ever picking close, so that on the arrival of winter hardy plants are ready to keep up a supply during the worst period of the year. It has to be noted that sufficient plants are left in the seed rows to carry the supply forward from June until the main crop is ready. When grown in rich soil it is sure to go down during winter, and in spring nothing is left to gather. Poorly grown plants stand ordinary winters well, and hard ones if protected with loose bracken scattered thinly over them, and in spring they are still in perfectly good condition, and capable of carrying on the supply until the spring sown plants are ready. Remove the flower stalks as they appear, and a slight dressing of manure applied from the middle of March up to the beginning of April has a wonderful effect.

It is at this period of the year that plants from a second sowing made in the beginning of August as the very latest date come in useful. The leaves are not large, but they are fresh and prevent a blank which might otherwise occur. The seed is sown

thinly in rows, and little trouble is occasioned by this crop if lines are drawn on a quarter of newly dug Potatoes, no digging or other preparation being required apart from levelling the ground and raking it even.—B. R.

THE JACOBÆA LILY.

THIS is a bulbous plant with curiously shaped and rich scarlet flowers, and like many other members of the Amaryllis family may be had in flower all through the winter months, and hence be extremely useful. It is usually catalogued as Amaryllis formosissima, but its correct name is Sprekelia formosissima, and it hails from Mexico. It is certainly to be regretted that their beautiful flowers fade so quickly, but although they only last from four to six days they are nevertheless useful where choice flowers are required for cutting or for the decoration of conservatories through the winter. We find that established bulbs will expand their flowers in from four to six weeks after starting the bulbs in a temperature of 65° to 70°, but as soon as the flowers are open the plants should be removed to a cooler house. They may be grown singly in 5-inch pots, but as each bulb only throws up a one-flowered scape it is best to place about five bulbs in a 7-inch pot, especially if required for decorative purposes in a large house, or even for cutting purposes. The flowers usually appear with the leaves, and like all Amaryllises they are best when established and their pots are full of roots; indeed, they should be forced gently the first year they are potted, and, with an eye to future usefulness, they must be well cared for after flowering.

This is where many people fail with bulbous plants. As soon as the flowers have faded, and this is generally at an early stage of the plant's growth for the season, they are thrown aside and neglected. We know, alas! too well that it is impossible to do justice to the host of dissimilar plants that have to pass through the gardener's hands, especially during the forcing season; but this does not alter the fact that unless the embryo flower be formed in the bulb before the leaves die, forcing or even natural growth, so far as flowers are concerned, will be a disappointment the next year. We find three parts loam and one part each of leaf mould and sand a good compost for this Sprekelia, but it will only require potting every second or third year, and if the surface soil is removed every season before starting the bulb and fresh compost supplied, also all suckers removed and the drainage kept free, they will flower for years without being potted. After flowering keep the plants well exposed to the sun until growth is completed, then gradually withhold water, and finally dry them off and rest them for at least three months.—J. H. W.

TREATMENT OF MANURES, SOILS, AND CROPS.

ONIONS.

It is not difficult for old gardeners to grow any vegetable produce in a garden they are acquainted with, but it will often put an old practitioner in a fix when he is transferred to a strange soil and locality, and the most successful cultivator is often overtaken in his old haunts with a series of failures, and that with a crop he has been unsurpassed in growing before. I could give many instances of this. How much more necessary, then, is it to instruct young beginners or fresh comers into certain localities as to the varieties suited to that part. Yet when a practical writer and gardener (say from the south) gives his experience and treatment, someone from the north or east or upon a different soil writes and contradicts him because he has grown a plant under different treatment with excellent results. That is also the case with most artificial manures; what one proves beneficial another fails with, but home manure is sure to suit the soil and crops in its district. Supply plenty in good condition, well work the soil, and the best results will be obtained. I was struck by seeing some twenty loads per acre of home or farmyard manure being placed upon the land by an artificial manure manufacturer. Yet he gave good dressings of these at the proper time, and no doubt secured a return that satisfied him; but in my opinion more disease has been created amongst vegetation by these manures than we are aware of.

For Onions make use of the Celery ground well manured. Deep digging will do, but it is best if the soil can be turned up from the bottom, using soot and lime. Sow spring Onions in February; make the ground firm before sowing, and roll after. The best method that I have found to act is either sow right through or cut them into beds by hoeing a path every 4 feet at right angles to the drills, or first mark out the paths and draw drills the length of the ground, and miss the path when sowing. The advantage of this is that Onion beds, being a nursery for weeds, these paths, which are only 1 foot wide, offer an easy

way for a man to walk up and use the Dutch hoe. Being at right angles to the drills the weeds can easily be drawn and carried out by the paths, whereas if the walks are parallel to the drills it is much more difficult to hoe and clean them. The varieties I prefer are James's Keeping, White Spanish, and Brown Globe, but this depends upon the soil. Bedfordshire Champion, Magnum Bonum, or Rousham Park are very good for light soils. Great care should be taken when hoeing not to cut the soil from under the Onions, and no one should be allowed to walk amongst them except by the paths, as they are injured by being knocked down.

One of the greatest enemies we have to contend with is the Onion fly or maggot. With this prevention is better than cure, and if liquid manure from stable cesspools is sprinkled over them, so as to settle in the axil of the leaf, it will be found that the fly will not deposit its eggs there. Petroleum mixed with water can be sprayed on with a syringe, or the petroleum can be mixed with a little softsoap and soda in hot water. Drenchings of liquid manure should be given in warm and dry weather. Water them on the foliage with a coarse rose. It is easy with good management and season to grow from 24 to 30 tons per acre. Autumn or Tripoli Onions should be sown in August, and transplanted as soon as large enough upon a warm border, and if well seen to and watered during the following summer Onions up to 20 inches in circumference will reward one's efforts. I have seen 30 tons per acre of spring and autumn Onions, the bulbs 22 inches in circumference, through proper attention being given them.

PARSNIPS.

To obtain good straight Parsnips the ground must be well worked in depth and pulverised. Too rich soil is injurious to them. Sow Hollow Crown and Student in February or early March.

CARROTS.

These can be treated the same as Parsnips. Carrots will crack badly if grown in too rich a soil. Sow Early Nantes the middle of February upon a warm border, and James's Intermediate or Veitch's Earliest the beginning of March, or at the same time as Parsnips. To procure good, straight, and long Carrots for exhibition crowbar a few holes, and fill with firm and fine soil, and sow seeds upon them. Do not be afraid of thinning either Parsnips or Carrots.—G. A. BISHOP.

TURNIPS.

FEW vegetables are more delicious than young quickly grown Turnips, and I think it may be safely said, at least of these, that there has been a marked improvement in the sorts which are grown now. No early variety can in any way compare with the Early Milan. This we begin sowing in small quantities in March, and though a crop or two may be lost through the plants rushing to seed, still we are favoured occasionally with an unexpected dish from an early sowing. To follow the above I do not know anything better than Early Snowball. This variety we sow in rapid succession all through the summer, finishing with two or three extensive sowings in August and September; these latter produce much-appreciated roots throughout winter and spring. I have tried a French variety of elongated shape called "Navet de Vertus;" this for winter work is exceedingly good. I think the flavour is better even than that of Snowball, and that is saying a good deal. This variety is sown early in August.

Turnips delight in a rich friable soil, and rapidity of growth is worth aiming at, as the flavour is so much improved by a quick growth. During summer sowings must be made not longer than ten days apart, so that nothing but young roots may be used. In dry weather the drills when drawn out should be well watered, a slight dressing of nitrate and superphosphate in equal proportions mixed with two parts of dry soil then sprinkled along the drills, and as soon as the moisture has dried sufficiently the seed may be sown thinly and covered with soil. When fly attacks this crop syringe or water through a fine rose with a weak solution of petroleum, softsoap, and water; dredge before drying with fine dry soil, in which one-eighth in bulk of tobacco powder has been mixed. Turnips, like many other crops, are ruined by thick sowing and late thinning. In dry weather it is safe to sow some thickly, but as a rule little seed is required. The plants when thinned need not be more than 6 inches apart, but even 2 inches less will suffice where space is limited. Where Celery is grown in quantity, say about 1200 to 1800 plants, there will be a long stretch of ridges between the trenches, and on these ridges Turnips do better than in any other position. We also grow them between rows of Peas, and for late autumn and winter supply sow seed alongside Spinach, Onions, &c., on ground cleared of second early Potatoes. Turnip tops are

sometimes used in spring as a substitute for Greens, and I have known Turnips placed in a Mushroom house to produce blanched tops, which were used instead of Seakale.—B.

A MUSHROOM FREAK.

DR. GEORGE WALKER of Wimbledon sends us a specimen of what he humorously calls *Agaricus acrobaticus*. One Mushroom is growing on the other, the backs being quite united, and the stalk of the upper one is better developed than in the illustration. Perhaps the worthy doctor is not quite able to account for the feat of agility performed by his fungological protégé, and we may inform him that the pair put their heads together under pressure when young and until they became united, then the stronger hoisted the weaker on its back, and thus in two respects supported it. Thirty years ago a similar specimen was submitted to us, from which the woodcut was prepared, and it was then stated that occasionally these monstrosities appear where Mushrooms

FIG 25.—A MUSHROOM FREAK.

are largely grown, and it seems to be due to a strong one in a crowded clump forcing one of the smaller ones up. The surfaces became united, and the upper one derives its support from its stronger rival.

MAIDENHAIR FERNS.

As this is the time of the year when the general potting of Maidenhair Ferns is done a few lines on my method may be of service to beginners. I say general potting, because in some gardens they are potted in spring only, and then are all given a shift on. I have seen Ferns which have been grown in the same pots for several years, and have done well, too, with a little soot-water occasionally given them while they were making their growth, but they make finer fronds and larger plants with an occasional shift. I find young plants better for at least two shifts during the year. Many gardeners use peat in their compost for potting, but they are much better without it. How is it that peat is so often recommended to be mixed with loam for potting plants of many kinds (other than Ferns)? It is natural for some plants to grow in peat and others in loam, but it is not natural for many plants to grow in a mixture of peat and loam. The composition of one is very different from the other; I believe it is sometimes mixed because the cultivator is not sure which is the natural soil it is found growing in. Sometimes peat is used to lighten heavy loams; when that is its only use I think leaf mould would be preferable and more natural, but it is surprising how some plants will grow in either peat or loam. Some may say Maidenhairs have grown well with them for many years in peat and loam mixed, and so they have with me, but they have been much better without peat.

I find they are best in a heavy turfy loam two parts, one part coarse silver sand, one decayed leaves (not leaf mould), but leaves

decayed into flakes, which may be broken by rubbing through a half-inch-mesh sieve. The turf is best picked to pieces by hand, and that which drops out in the operation should be put aside for other purposes. The compost must be well mixed and placed in a house to be warmed. The pots also must be washed, crocked, and taken in the house, and, when convenient, the potting should be done in the house at this time of the year. Small shifts are the best for Ferns, leaving just room to force the soil down with an old label only moderately firm. I was taught to pot Ferns very firmly, and when there is plenty of peat in the compost they can be potted more firmly than when heavy loam without peat is used. Take care in potting that the ball is of sufficient depth that the new soil can be level with it exactly, for if it is above the new soil the water will run through and leave the ball dry, and if it is lower the soil will work into the crowns.

When plants have become too large they are sometimes divided and placed into small pots, but they do not take to the soil very readily; the roots are cut about so much that they have to form new ones, during which time the crowns are much exhausted. I find it is a better plan to raise plants from spores, and it is astonishing how soon they make good plants. I have useful plants for decoration (in 60-size pots) that came from spores sown only thirteen months ago, and some have been potted into 48's, while others are only in thumb pots, but even these are prized for placing in small vases. Divided plants cannot often be had in such small pots for usefulness in the house.

I have tried many plans of raising plants from spores, but only the one which is simple and the most successful is needed. I procure a deep pan and place a little good drainage in the bottom; some heavy turfy loam is then obtained, which is pulled into pieces about the size of pigeon's eggs. These are stirred about in a box of silver sand, so that as much as possible can stick to them. I then pack them closely and rather firmly together in the pan, but leave the surface quite rough and about an inch below the surface of the rim of the pan. It is then well watered with a fine rose, and the seed spores are sown upon it; the pan is then covered with a square of glass and kept in a shady place in a temperature of 60°. The pan is occasionally dipped into a tank of water, so that the water can gradually rise to the surface from the bottom, taking care that it does not rise above the surface of the soil to disturb the spores. When the seedlings are well up the glass is tilted, and the plants are gradually brought to the light, but it is better to let them attain a fair size for handling before potting them singly into thimble size pots, and when this is done they should be kept rather close and shaded, but do not damp them overhead while being kept close. In fact, I never wet the foliage at any time if I can avoid it, but they enjoy a moist atmosphere at all times.

—J. L. B.

EVENTS OF THE WEEK.—The spring shows will shortly be occupying the attention of horticulturists, but at present engagements of a special character are not numerous. The following Society meetings take place during the week;—The Royal Society on Thursday at 4.30 P.M.; the Quekett Club on Friday at 8 P.M.; and the Society of Arts on Wednesday, March 5th, at 8 P.M.

— **A HALL FOR HORTICULTURE.**—In reference to this matter we have received from the Secretary of the Royal Horticultural Society a circular now being issued to the Fellows, and explaining the project of which an outline was given in this Journal, page 123, February 13th. The document reached just as we were going to press, so that we can only give the following paragraphs:—"It is proposed to invite all friends of horticulture to join together in placing in the hands of three Trustees (of whom Baron Schröder is willing to be one) a sum of £40,000, to be held by the Trustees free of interest for the benefit of the Society, and to be gradually returned to the lenders by annual drawings of the bonds which they will receive from the Trustees. The drawings to commence, it is hoped, two years after the opening of the new buildings. Of this sum of £40,000, the greater part would be invested by the Trustees in first-class securities, yielding interest, and the remainder would be invested in the buildings to be erected, the Society paying rent for them, and the total of interest and rent thus received by the Trustees would suffice for the payment

of the ground rent. It is hoped that a considerable sum would be annually obtained for the purpose of redemption of bonds by letting the basement and the great hall itself for various purposes at times when it was not required by the Society." We are glad to notice the following additions to the list of subscribers already published. Sir Trevor Lawrence, Bart., M.P., £250; Messrs. James H. Veitch and Arthur J. Veitch, each £50; Mr. W. Marshall, £25; Messrs. Hurst and Sons, £200; and Messrs. Seeger & Tropp, £25.

— **SEVERAL** bright days have been experienced in the METROPOLITAN DISTRICT, but some unusually thick fogs have also occurred on one or two mornings. Slight frosts in the morning, with somewhat keen north-easterly winds have been the rule. The ground is in good condition except in low-lying districts.

— **THE WEATHER IN THE NORTH.**—February 17th-24th. The first days of the week were dull and cold, with east wind. Sleety showers fell in the afternoon of the 20th. Since the middle of the following day the weather has been delightful, with slight morning frosts. The 23rd was lovely, the air full of sunshine and song. The barometer for a day or two has been unusually high.—B. D.

— **THE** schedule of the RICHMOND (SURREY) HORTICULTURAL SOCIETY'S SPRING SHOW announces that the dates are Tuesday and Wednesday, March 18th and 19th, and the place selected is the Castle Assembly Rooms. Thirty-six classes are enumerated, with three prizes in most of them, for Hyacinths, Tulips, Narcissus, Azaleas, Cyclamens, Spireas, Dielytras, Deutzias, and other forced plants. Numerous special prizes are also offered, and those who remember the very attractive display provided last year can only desire an equally successful repetition. Of the metropolitan local Societies, Richmond is the only one that includes a Spring Show in their programme, and the experiment is well worthy encouragement. Mr. J. H. Ford, 22, George Street, is the Hon. Secretary.

— **AN** ordinary meeting of the ESSEX FIELD CLUB will be held in the Loughton Public Hall on Saturday evening, March 1st, 1890, at seven o'clock. After exhibitions a paper will be read:—"The Micro-Fungi of Epping Forest; How to collect, preserve, and study them." Section I., The Uredines. Section II., Myxogasters. By M. C. Cooke, Esq., M.A., LL.D., A.L.S., &c. The paper will be illustrated by specimens, and members having microscopes are asked to bring them, so that the smaller forms may be shown. Dr. Cooke's discourse will be the second of a series which the Council intend to promote from time to time, with the object of inciting and advising members to the selection of lines of practical biological and geological study. Exhibitions of objects of natural history, geology, or microscopy are solicited for the above meeting. Intending exhibitors are requested to communicate with the Hon. Secretaries.

— **BIRMINGHAM GARDENERS' ASSOCIATION.**—At a meeting on February 18th Mr. W. Spinks read a paper on the Tomato, giving full cultural instructions, together with a list of varieties he had from experience found best. Reference was made to the successful culture of the Tomato at Chiswick, and the single rod system was advocated by Mr. Spinks, as well as by others present. A good practical discussion followed.

— **OSIERS AND FRUIT TREES.**—Owing to the leniency of our officials with criminals who plunder our gardens fruit-growing with us in many cases has become a thing of the past. As a screen from public view to my garden, and at the same time affording honey and pollen to my bees, I planted Willows of sorts on one side of it; close to a Pear tree I planted some of the "rat-tail" sort, which forms quite a thicket, yet the Pear tree so surrounded never produced a finer crop than it did last autumn, corroborating all Mr. J. Wright says in the leader of February 20th. But what about the use of Willows for paper making? Apropos of fruit-growing, the question of planting has not been fully exhausted. There are two planting times recommended—viz., at the fall and during February or March. In making a new plantation, in addition to deep tilth and drainage, I consider it of the greatest importance to begin planting at the end of September and finish not later than the middle of October. My reason for this early work is that with early mulching at the same time the rootlets are bent on coming near the surface, which, owing to the earliness, are produced abundantly before the foliage drops. When planted later rootlets are not formed, and if delayed till March the ground is often so dry as to cause the rootlets to descend for moisture.—W. T.

— **TRADE ANNOUNCEMENT.**—Mr. H. J. Jones, until recently in partnership with Mr. N. Davis at Camberwell, has now commenced business on his own account at the Ryecroft Nursery, Hither Green, Lewisham.

— **MESSRS. B. S. WILLIAMS & SON** send us examples of their Meteor strain of Primulas, red, white, and blue. The flowers are of good form and substance, the darker colours rich and bright, and the white pure, without any suffusion.

— **GARDENING APPOINTMENT.**—We are desired to say that Mr. H. Dunkin, whose appointment was announced recently, decided not to remain at Porter's Park, and that he has been succeeded by Mr. W. W. Edwards, formerly gardener to A. H. Lancaster, Esq., Honeylands, Waltham Abbey, Essex.

— **EARLY LETTUCES.**—A French correspondent who has been interested in Mr. Bardney's article on Cos Lettuces (page 112) states that a new "Early self-folding Trianon, a little shorter than Paris White, but large, firm, some days earlier, and slow to run to seed, is being sent out this year by Messrs. Vilmorin." The variety will probably be obtained by English seedsmen and find a place in our gardens.

— **MR. ARTHUR H. KETTLEWELL** sends us a manual on the art of **LANDSCAPE GARDENING**. It comprises three short essays, the first dealing briefly with the general principles of the art, the second on the different kinds of gardens, and the third on practical work. It is a very short epitome of a great subject, and contains suggestive hints on garden arrangements and planting. Mr. R. W. Satchell, Kingston, is the publisher.

— **FRAGRANT FERNS.**—R. I. L. writes:—"Whatever the merit of *Dryaria Willdenovi* may be in point of perfume, there is nothing perhaps among Ferns that can equal the delightful odour of *Nephrodium fragrans*. It is not often, but it is sometimes met with in hardy and greenhouse collections. The perfume is to me much like that of Violets. It is quite a small plant with fronds, in cultivation, of only a few inches in length. It is native from the Caucasus to Kamschatka, and from Arctic America down to Wisconsin."

— **THE Report of the ROYAL SOUTHAMPTON HORTICULTURAL SOCIETY** for 1889 shows a favourable balance on the year's working, but the summer Show appears to have cost the Society £498, and to have produced £421, not a very satisfactory result. The annual subscriptions are £332. The deficit in receipts is attributed to the bad weather which prevailed on the Show days. The annual general meeting of the members will be held in the small hall, at the Philharmonic Rooms, on Thursday, February 27th, at 7.30 P.M., to transact the following business:—To receive the annual report and statement of accounts; to elect the officers for the current year, also five members to serve on the Council (not less than two of whom must be gardeners).

— **THE WEATHER AND SPRING FLOWERS IN THE ISLE OF WIGHT.**—Mr. C. Orchard, writing from Bembridge, says:—"We are having some cold easterly winds that are keeping the early vegetation back. The spring flowers were very early out of doors. Snowdrops and Crocuses are nearly over. The single and Campernelle Jonquil have been in bloom for some weeks, and to-day I have seen clumps of *Anemone coronaria* and the *Polyanthus Narcissus* in full bloom, also *Myosotis distiflora* and other spring flowers equally as forward. The *Veronicas*, in different varieties, bloom here all the winter, also *Coronaria glauca*, and at The Castle, St. Helen's, to-day I saw a fine plant of *Genista* (*Cytisus*) well out in bloom on all the points. They stand out here all the winter and bloom profusely in the spring."

— I BEG to ask my brother gardeners through your valuable paper if they have had any practical experience in the successful eradication of **YARROW FROM LAWNS**; if so, may I trouble them to enlighten me? I have a large patch of Yarrow in one of my lawns, which keeps spreading year by year. I have so far been unable to check it. Two years ago the lawn being rather poor I gave it a good dressing of bone dust; later on a good dressing of guano. I also watered it on several occasions with diluted liquid manure, and last year I gave it two dressings of Watson's lawn sand, which for the time appeared to kill it outright; but it sprang up again, and is now more vigorous than ever. I cannot see any other plan but lifting the turf and replacing fresh. If any gardeners have been successful in the eradication of Yarrow I shall be very pleased if they would give me and many others the mode of procedure through our valuable medium, the

Journal of Horticulture. They will greatly oblige one at any rate who would appreciate their kindness.—GEO. CORBETT.

— **THE WILDSMITH MEMORIAL FUND.**—We learn that in connection with the Reading and District Gardeners' Mutual Improvement Association the following Committee has been appointed to carry out the suggested memorial:—President, W. J. Palmer, Esq., J.P. Committee—Chairman, W. J. Palmer, Esq., J.P.: Messrs. W. Baskett, J. Coombes, T. E. Henwood, C. Holt, W. Lees, J. Martin, J. Pound, and G. Stanton. Hon. Treasurers, Arthur W. Sutton, Esq., and Harry J. Veitch, Esq. Hon. Sec., Mr. T. Turton, The Gardens, Maiden Erlegh, Reading. It is promoted in memory of the late Mr. Wildsmith by some of his attached friends for the purpose of placing on the Gardeners' Orphan Fund a child to be known as the Wildsmith Memorial Orphan. It is earnestly hoped that there will be a very ready response to this appeal by all the gardening friends and admirers of Mr. Wildsmith throughout the United Kingdom. The Committee venture to suggest that Mr. Wildsmith having promised his friend Mrs. Hyde that he would do his utmost to place a second child of hers on the Fund (one having been already elected through his instrumentality), they cannot do otherwise than endeavour to carry out their late friend's wishes, and they sincerely trust that a promise made under such peculiarly touching circumstances will commend itself as the most fitting memorial to him that can be raised. At least £130 will be required to enable the Committee to attain the object they have in view.

— **THE first part of the Memoirs and Proceedings of the Manchester Literary and Philosophical Society** for the current session has been issued. It contains a paper by Mr. Charles Bailey on the discovery near Ribbleshead of *ARENARIA GOTHICA*, a plant new to Britain, the typical form of which has so far been recorded only for two Swedish localities. The Ribbleshead specimens are stated to be more robust than those from Sweden. The issue also includes a paper by Mr. Charles H. Lees on the law of cooling and its bearing on the theory of heat in bars; and the first part of Mr. Faraday's "Selections from the (unpublished) Correspondence of Colonel John Leigh Phillips, of Mayfield, Manchester" (1761-1814). The latter includes letters from Dr. Henry Clarke (the mathematician), James Sowerby, and a number of other persons of local eminence during the latter half of the last century. —(Nature.)

— **EARLY SNOWDROPS.**—Observing the remarks by "W. E., *Rutherglen*," anent Snowdrops, I may say that the plants to which I alluded are all seedlings and distinct from their parents. The one in full bloom on the 8th January being the earliest of any Snowdrop, and others a few days later the largest and prettiest I have seen. Snowdrops have not had the attention paid them they deserve to ensure their improvement. I believe that by careful crossing a great advance in that welcome harbinger of spring will be effected. In a direct line at a mile distant two ways, north and south from me, Snowdrops were in full bloom at the end of December, and double Primroses have been fresh throughout the whole winter in my own garden. Change the position of these Snowdrops, and the earliness of mine, flowered on January 8th, will be apparent. A little sometimes hastens or delays the maturing of plants and flowers. There is only a hedge about 6 feet high which separates my garden from a plantation of Gooseberries, Currants, and Strawberries, and invariably they ripen at least a week earlier than the same varieties in my garden do. Extra manuring in my case may help to this, but the main cause is, I think, a better exposure to the rising sun.—W. T.

— **CABBAGES AT THE WAKEFIELD PAXTON SOCIETY.**—Considering the unfavourable weather which prevailed, a goodly number of the Paxtonians assembled at their rooms at the Saw Hotel to listen to a paper on "The Cultivation of the Cabbage," which had been prepared and was read by one of the Vice-Presidents of the Society—Mr. J. G. Brown, head gardener to J. B. Charlesworth, Esq., J.P., of Hatfield Hall. Mr. H. Oxley, the President, occupied the chair, and Mr. B. Whiteley was in the vice chair. Mr. Brown dealt with his subject in a thoroughly practical manner, indicating the best varieties to use, the mode of raising young plants, the preparation of their permanent quarters, the most suitable soil, and the requisite preparation, manuring, &c. An interesting discussion ensued on the paper, in which the Chairman and Vice-Chairman, Messrs. Pitt, Gill, Garnett, Kingswell, Pickersgill, Pye, and others took part. In the course of the discussion some remarks were made with reference to the cooking of the Cabbage, and it was said by some of the speakers that many persons spoil Cabbage in consequence of improper attention to its preparation for the

table. On the motion of Mr. G. W. Fallas (one of the Hon. Secs.), seconded by Mr. Pitt, a very hearty vote of thanks was accorded to Mr. Brown.

— **TOO SUCCESSFUL A PRIZEWINNER.**—As your correspondents do not in my opinion give a satisfactory solution of the above problem, I venture to offer my opinion how this difficulty can be overcome. The Judges may be asked to give their opinion as to the four best exhibits in each class, and the Committee empower two of its number to follow the Judges and decide any first prizes secured above a given number. A special prize should be given to any first prize secured by the too successful prizetaker, and the following three should be awarded the first, second, and third. The funds must be considered. This is the work of the Committee, and can be adjusted according to the funds at disposal. I question the wisdom of Mr. Thomson's remarks on page 118. There would be no difference only in honour, and the exhibitors might as well say it is only a question of 5s. difference between us, and we might as well consider ourselves all equal and ask the lovers of horticulture to subscribe for a present all round. Like my friend Mr. Bates, the total at the end of the season would be more important to me than the honours, though we all like to be first. If the losing of first prizes is not sufficient to move the hinder ones they are not worthy of taking honours others are entitled to. If it is a question of rich and poor cottagers make separate classes.—G. A. BISHOP.

— **RETIREMENT OF A SUCCESSFUL EXHIBITOR.**—There are few, if any, better known gardeners in the west of England than Mr. G. Lock, Newcombe House, Crediton, Devon, and the news that owing to a great increase in his duties he contemplates retirement as far as the cultivation and exhibiting of specimen plants are concerned will be received with widespread regret. He has finally decided not to compete at any more shows, and there can be no mistake about this, as the principal portion of specimen plants are to be sold privately as fast as customers can be found for them. As a rule there are always men ready to take the place of those willing to make room for them, but it is very doubtful if Mr. Lock's grand plants, of which I have seen as many as four large vanloads at one show, will not be badly missed for several seasons. Since hearing of Mr. Lock's decision, and which was not altogether unexpected, I have ascertained from him a few facts that may be of general interest. He has competed at various shows, though principally at Taunton, Exeter, Southampton, Weston-super-Mare, Plymouth, Torquay, and Calne, during the past fifteen years, and has won no less than 616 prizes, out of which number there were 432 firsts. Of the latter sixty-three were for collections of stove and greenhouse plants, forty-nine for fine-foliaged plants, fifty for exotic Ferns, forty-three for groups arranged for effect, thirty-four for single specimen plants, thirty-seven for vegetables, and fifteen for Pine Apples. This will, I think, be considered a very good record for a private gardener, and represents an extraordinary amount of skilful culture, ability in packing and staging, and very hard work.—W. I.

— **CULTIVATING THE ORCHARD.**—A correspondent of the "American Cultivator" writes:—"The orchard is generally supposed to be a place to be utilised for several purposes. If farmers were satisfied to grow a single crop in the orchard, as they are in respect to cereals, there would be fewer complaints about the unprofitableness of fruit; but they always seem desirous of procuring a crop of fruit and a crop of grain or grass from the land also. Now, as the land is no more capable of producing two good crops when used as an orchard than when occupied by other crops, there is no reason why an orchard which includes the land in one sense should be afflicted with more than it should produce. But as the space between the trees seems to be unoccupied, though really not so, the farmer is tempted to put in a crop of grass, grain, or vegetables, and wonders why the orchard is so unproductive. The production of a large crop of fruit deprives the soil of a large quantity of mineral matter, especially potash, and although the trees themselves seem to occupy but a limited space, with their branches in the air, nevertheless the roots occupy every portion of the ground, and are at work upon every atom of available nutritious matter that can be taken from the soil. To add a crop of grass is but subjecting the land already heavily taxed by the trees to the production of two crops. The reason why some orchards flourish while standing in grass is because the demands of the trees and of that particular kind of grass are dissimilar, yet in the course of time one exhausts the soil of that which the other requires. Trees do not require stable manure unless it is well rotted, but an application of lime or wood ashes in the spring and fall, with the surface kept clean with a cultivator, will

greatly improve the trees, and also the quality of the fruit. The plough should not be used by running too deeply, since it tears up and destroys the roots. All the orchard wants is occasional cultivation and a close pruning once a year. Another point to be observed is that of thinning the fruit from young trees when they are too heavy laden. If this is done that remaining will be of a better quality and finer in appearance. In nearly all cases where orchards fail the cause may be traced to mismanagement."

— THE usual monthly meeting of the ROYAL METEOROLOGICAL SOCIETY was held on Wednesday evening, the 19th inst., at the Institution of Civil Engineers, 25, Great George Street, Westminster. Mr. O. B. Cuviiljé, Mr. W. Harpur, M.Inst.C.E.; and Mr. H. J. Spooner, F.G.S., were elected Fellows of the Society. The following papers were read—viz., 1, "Observations on the Motion of Dust, as Illustrative of the Circulation of the Atmosphere, and of the Development of Certain Cloud Forms," by the Hon. Ralph Abercromby, F.R.Met.Soc. The author has made numerous observations on the motion of dust in various parts of the world, especially on deserts on the west coast of South America. He finds that the wind sometimes blows dust into streaks or lines, which are analogous to fibrous or hairy cirrus clouds; sometimes into transverse ridges and furrows, like solid waves, which are analogous to certain kinds of fleecy cirro-cumulus cloud; sometimes into crescent-shaped heaps with their convex side to the wind, which are perhaps analogous to a rare cloud form called "mackerel scales;" sometimes into whirlwinds, of at least two, if not of three varieties, all of which present some analogies to atmospheric cyclones; sometimes into simple rising clouds, without any rotation, which are analogous to simple cumulus topped squalls; and sometimes into forms intermediate between the whirlwind and simple rising cloud, some of which reproduce in a remarkable manner the combination of rounded, flat, and hairy clouds that are built up over certain types of squalls and showers. Excessive heating of the soil alone does not generate whirlwinds, they require a certain amount of wind from other causes to be moving at the time. The general conclusion is that when the air is in more or less rapid motion from cyclonic or other causes, small eddies of various kinds form themselves, and that they develop the different sorts of gusts, showers, squalls, and whirlwinds. 2, "Cloud Nomenclature," by Capt. D. Wilson-Barker, F.R.Met.Soc. The author proposes a simple division of cloud forms under two heads—viz., cumulus and stratus, and recommends that a more elaborate and complete division should be made of these two types. A number of photographs of clouds were exhibited on the screen in support of this proposal. 3, "An Optical Feature of the Lightning Flash," by E. S. Bruce, M.A., F.R.Met.Soc. It has been stated in the report of the Thunderstorm Committee of the Royal Meteorological Society that there is not the slightest evidence in the photographs of lightning flashes of the angular zigzag or forked forms commonly seen in pictures. The author, however, believes that this is an optical reality, as the clouds on which the projection of the flash is cast are often of the cumulus type, which afford an angular surface. In support of this theory he exhibited some lantern slides of lightning playing over clouds.

DENBROBIUM MACFARLANEI.

THIS exceedingly distinct and beautiful Dendrobium was exhibited by Messrs. J. Veitch & Sons at one of the recent meetings of the Royal Horticultural Society (January 14th, 1890) when a first-class certificate was awarded it by the Orchid Committee.

It is thus described in "The Manual of Orchidaceous Plants." Stems erect, sub-cylindric, 5-8 inches high, usually rarely triphyllous. Leaves oblong, sub-acute, leathery, 3-4 or more inches long. Racemes ascending, 9-12 or more flowered. Flowers among the largest in the genus, 4-5 inches across; sepals and petals white, the former lanceolate, the latter longer and broader, sub-rhomboidal, acuminate; lip nearly as long as the petals, three-lobed, the side lobes basilar, oblong, white with a large purple spot at the anterior margin; intermediate lobe euneate-oblong, acute, white, purple at the base, as is the ligulate furrowed callus. Column white, bordered with purple on each side of the stigmatic cavity.

A beautiful species sent to us, in 1882, from the Papuan Institute, in Torres Straits, by the Rev. S. M. Macfarlane, to whom it is dedicated by Professor Reichenbach. Its discoverer was the late Mr. Hartman, of Toowoomba, Queensland, to whom botany and horticulture are indebted for many plants gathered by him for the first time in North Australia, and in the south-east peninsula of New Guinea, the supposed habitat of this *Dendrobe*. Owing to the exhausted condition in which the few plants that survived the long journey reached us, none have yet flowered, but one derived from another source flowered in the autumn of 1886, in the collection of Mr. J. N. Hibbert, at Chalfont Park, near Slough.

complete its growth, withholding water gradually while the period of leaf-falling advances; afterwards they get no water during the winter, only what is deemed sufficient to prevent shrivelling. They remain in a warm greenhouse through the winter until the buds begin to swell, when they are shifted into the stove. A plant that a little over a year ago cost 1s. 6d. furnishes us with eighteen of its distinctly pretty flowers this year.—W. S.

DENDROBIUMS.

PLANTS that have flowered must be watered with great care. Injury often results in their present stage from giving them too

FIG. 26.—DENDROBIUM MACFARLANEI.

DENDROBIUM PARISHI.

FOR amateurs who cultivate Orchids under the mixed plant stove conditions the above plant has much to recommend it, inasmuch as blooming is certain and culture easy when carefully attended with a due supply of water during the period of growth. It is of good constitution, and under generous treatment a good pseudo-bulb from 18 inches to 2 feet or more is available, that will give blooms from every joint without the risk of reverting to growth as is the case with many sorts, particularly *D. nobile*. The sepals and petals are of a dark lilac shade, having a crystallised surface sparkling in the sunshine. The lip is white, of a woolly nature, the edges recurving, giving it a distinctly striking appearance. It requires to be grown in a basket because the growth is strictly pendulous, and shows to greater advantage suspended from the roof when in flower. It grows well in fibrous peat, sphagnum moss, and charcoal or crocks, and shaded during the summer. In the autumn we place this Orchid with others in a greenhouse to

much. The roots of many are still inactive, and if they are kept in a wet state numbers are certain to perish. The reason many *Dendrobiums* decline in health after the first or second season is frequently owing to keeping them in a saturated condition as soon as flowering is over and the plants commence growing.

They need little water at first, a slight dewing with the syringe being ample in a moist atmosphere until the formation of new roots. As the roots and growth extend the supply of water should be increased. Plants would last longer and increase in strength if greater care was exercised during the early stages of growth, and again after the completion of growth. When *D. nobile* starts into growth it often pushes growths freely from the pseudo-bulbs. If these are not wanted for stock they should be removed, for they have a tendency to rob the growths that issue from the base. This old but very useful Orchid delights in a moist atmosphere. It refused to grow with us in a little house that is naturally dry, where *D. crassinode*, *D. heterocarpum*, *D. chrysotoxum*, *D. suavis-*

simum, *D. densiflorum*, *D. thyrsiflorum*, and others flourished. The plants were afterwards grown in a moist warm border of a plant stove, and they quickly attained their original strength.

MANURE FOR ORCHIDS.

It is no new thing to use manure in the compost for terrestrial Orchids. It has been recommended and practised in gardens for twenty years to my knowledge, and with the best results for *Calanthes*, *Bletias*, *Phajus*, *Cypripediums*, and others. Cow manure carefully prepared and added to the compost is a decided advantage with such plants as *Cypripediums* of a strong growing nature. It is best to use it near the surface, so that at the end of each season any that remains can be readily removed. Manure in a liquid state, made from steeping cow manure in water, has been repeatedly given to these plants with the most beneficial results. Soot water in a clear state is stimulating also. A bag of soot steeped in a tank with cow manure and used in a weak state is a splendid stimulant. We have tried its effects, not only on *Calanthes*, *Bletias*, and *Phajus*, but frequently on *Cypripedium* insigne. With the latter, plants as nearly equal in all respects as possible were selected, and some watered with the liquid during the season of growth, and the others with pure water only. The stimulant had the effect of producing finer growth of a deeper colour and larger flowers. This liquid is also good for *Cœlogyness*, *Lycastes*, and strong-growing *Zygopetalums*. We do not doubt that suitable artificial manures would also be beneficial to these plants. We have tried some that have been recommended for this purpose, but prefer the manure and solution that has been referred to. We have grave doubts, however, about using artificial manures in the compost for epiphytall Orchids. As a rule these manures are too forcing in their nature. We should certainly prefer weak liquid from cow manure. This we syringe amongst the pots and about the floors of the house, to be evaporated and taken up by the plants from the atmosphere. This note is intended as a warning. The successes in some quarters may lead to a wholesale system of feeding with manure and stimulants, and result in more harm than good. My advice is, Use manure and liquid to the class of Orchids I am considering cautiously. When we look at the excellent results attained by good culture without manure or liquid in the case of epiphytall Orchids we have grave doubts of any improvement to warrant the risk. In some cases—*Dendrobiums* for instance—larger pseudo-bulbs and foliage may have resulted, but whether this is an advantage remains to be proved. It is wise to experiment in this matter, for by so doing only can reliable knowledge be obtained. But before the practice is taken up generally it is necessary to know whether strong growths and bold foliage made under pressure by the aid of forcing artificials are likely to prolong or shorten the life of the plant.—ORCHID GROWER.

ROYAL HORTICULTURAL SOCIETY.

SCIENTIFIC COMMITTEE.—Present: W. T. Thiselton Dyer, Esq., in the chair, and Professors Michael Foster, A. H. Church, H. Marshall Ward, D. H. Scott, Messrs. G. F. Wilson, T. Francis Rivers, H. J. Veitch, W. F. Blandford, R. McLachlan, Dr. Oliver, and D. Morris.

Mealy Bug at Alexandria.—Mr. Morris supplemented the information already given by him respecting this new Egyptian pest by reading a letter from Mr. J. W. Douglas, to whom the specimens had been sent, stating that the coccids had proved to be not only a new species, but a new genus. It was proposed to describe them under the name of *Crossotoma ægyptiacum*.

Growth on Stem of Cattleya.—Mr. McLachlan reported on a peculiar growth on the stem of a *Cattleya* from Brazil. This was at first supposed to be of the nature of a cocoon, but a careful examination of the structure had shown it to be a gall. Professor Marshall Ward undertook to make further examination.

Sugar-cane borer at St. Vincent.—Mr. McLachlan drew attention to a disease in Sugar-cane at St. Vincent, where in some localities about 25 per cent. of the crop would be lost this year. According to Mr. Herbert Smith, who had examined the canes, a beetle of the family *Scolytidæ* and the larva of a moth, were concerned. It is probable that the beetles only enter the canes by the exit holes of the moths. The moth is probably a widely spread species already known to attack Sugar-cane into other countries. The affected canes should be burned, and steps taken to destroy the moth in the localities specially frequented by it.

Disease of Orchids.—Mr. Morris exhibited several specimens of a *Cattleya* attacked by a fungoid disease of apparently a very virulent character. From a specimen received about a fortnight ago Mr. Massee, at Kew, had infected two or three healthy plants, and in three days the whole of the pseudo-bulbs had become diseased. Specimens of similarly affected plants were sent by Mr. James Douglas from a gardener who was anxious to know if there was any remedy, as he feared his collection was in danger of being destroyed. The Committee was of opinion that the disease, whatever the cause, was of a very virulent character. It was not the ordinary "spot" so well known to Orchid growers. The

specimens were referred to Professor Marshall Ward, who had already given some attention to the subject.

Orchid Hybrids.—Mr. H. J. Veitch exhibited *Cypripedium Lathamianum* ×, raised first at the Birmingham Botanic Gardens, by crossing *C. Spicerianum* ♂ with *C. villosum* ♀. Messrs. Veitch had raised similar hybrids, and had, moreover, raised hybrids from the reversed cross. Plants from all the three sources were shown. These agreed so closely in all essential points that they must bear the same name. The fact of plants obtained by crossing, and also by reverse crossing, producing seedlings of almost exactly the same character, is very interesting. Similar results have been obtained by Messrs. Veitch in crossings which have produced *Cypripedium Sedeni* ×, and *Fuchsia Dominiana* ×.

Mr. H. J. Veitch also exhibited a new hybrid *Dendrobium*. The seed-bearing parent was *D. japonicum*, and the pollen parent *D. Wardianum*. The hybrid *D. Wardiano-japonicum* had smaller pseudo-bulbs than *D. Wardianum*, but the flowers were nearly those of *D. japonicum*, but larger and with broader segments. They were also highly scented, as in *D. japonicum*.

Canker in Apple Trees.—Professor Marshall Ward brought before the Committee specimens of Apple trees badly affected with the so-called canker, on which there were numerous red perithecia of a *Nectria*. It is probable that the initial injury in this case had been caused by frost, and that the *Nectria* had established itself in the cracks thus formed.

Picea nobilis.—Mr. James Douglas forwarded branches of *Picea nobilis* affected by gouty swellings, due probably to the attacks of an *Acarus* (*Phytoptus*), or to *Ædium elatinum*. Professor Marshall Ward kindly undertook to examine the specimens.

London Fogs.—Dr. Oliver and Professor Scott presented an interim report on the investigations undertaken by them respecting the effects of London fogs on plants under glass. Specimens of Orchids affected by fog had been received from Messrs. Veitch & Son, Chelsea; and of Tomato plants from the Superintendent of the Royal Horticultural Society's Gardens at Chiswick. On the suggestion of the Chairman it was decided to take up an investigation of the chemical constituents of London fog, and trace the exciting causes of the injury to plants. The question was a very important one, and demanding considerable time and attention. In order to carry out the work under advantageous circumstances, it was resolved to make application to the Government Grant Committee of the Royal Society for pecuniary aid.

[We did not receive the above report in time for insertion in our last issue.]

PLANTS FOR A VINERY WALL.

"M. G. D." (page 108) will find *Plumbago capensis* one of the best plants he can have for covering the back wall of his vinery. The temperature required for the Vines just suits this plant, for it does not mind shade, and both grows and flowers well under the conditions it has to endure in a house solely devoted to Grapes. We have it planted at the base of our Muscat vinery; the wall is 12 feet high, the border about 18 inches wide, and as much in depth. The soil is mainly composed of loam, leaf soil, and charcoal, with a sprinkling of finely ground bones, and receives a similar top-dressing annually. When the plants were placed out they were encouraged to grow freely, the shoots extended, and were tied to the wires or fastened to the wall their whole length, with a view to cover it as quickly as possible. When this has been effected all the additional shoots, which will grow away from the wall, should be allowed to hang downwards in a free manner, as trusses of bloom will be borne at the point of each shoot. After the first supply of flowers during the summer the shoots will make fresh growth, which will continue to produce flowers more or less well into the autumn. Abundance of water, both at the roots and over the branches, is necessary to promote free growth and cleanliness, as without it the leaves are sure to become infested with red spider, which not only spoils their appearance, but checks the free growth, upon which the season's flowers depend. When well established frequent supplies of liquid manure to the roots will be of much service in assisting a full development of vigorous shoots, deep green foliage, and abundance of large trusses of bloom.

From October until Christmas our plants are subjected to rather rough treatment. The space being required for *Chrysanthemums* we prune all the current year's shoots to within one or two eyes of the wall; from those remaining shoots are freely produced the next spring. The wall is then covered with tall *Chrysanthemums*, the leaves of which completely hide the *Plumbago* from sight. This seemingly rough treatment does not interfere with the success of the plants the next year, as when the vinery is put into order and "started" about the middle of February young shoots are freely made, and never fail to flower well. Sometimes green fly will attack the points of growth, and at times, perhaps when fumigating the house with tobacco smoke is out of the question owing to the Vines being in bloom, recourse must be had to syringing the *Plumbago* with soapy water or other insecticide, taking care that it is not used in too strong a state. I have seen a number of flowers spoilt by too strong an application of lemon oil, therefore I should like to caution the inexperienced against a mishap of this sort. The young leaves are tender, owing to their being grown in strong heat and without the aid of much sun to make them hardy, as under the Vines very little of the sun's influence is felt.

Up the back wall of a late vinery we grow Tomatoes, and manage to secure some fair fruits during June and July by having the plants 2 feet

high before they are placed against the wall; after that time the shade from the Vines is so dense that nothing but leaves and stems are grown. By starting the Vines about the 1st of March the Tomato plants are enabled to make a good growth and set some fruits, the plants being raised from seed sown early in the year before all the space devoted for the growth of the Vines is covered with foliage.

Asparagus tenuissimus is a capital plant for covering a back wall in a vinery, where greenery only is wanted. The feathery shoots of this climber are most useful for supplying "backing" to buttonhole bouquets or sprays, growing as it does in exactly the right form for this purpose; or for mixing with flowers in small vases it is good, being of such a deep green colour. But this variety cannot be compared with *A. plumosus nanus* for vase or epergne decoration. For covering walls as here described it is first rate, as it grows rapidly, sending out thick shoots from the base, which will quickly mount to the top of a 12 foot wall. Abundance of water is needed at the roots to ensure freedom of growth. If this attention is neglected the minute needle-like leaves will quickly turn brown and fall off, rendering them quite unfit for use, and disfiguring the appearance of the plant also. A compost of two parts fibry loam, one part of peat and leaf soil, with plenty of sand and charcoal, using the loam and peat as rough as possible, will suffice to grow this plant well. As before stated, abundance of water is essential to success. To hide the soil in which this *Asparagus* is growing we plant annually in the spring *Panicum variegatum*, which grows freely and makes an agreeable contrast to the deep green of the climber.

Hoya carnosa will succeed in the same position with a soil composed mainly of peat, leaves, a fourth part of loam, and a good dash of bone meal. When planted out and given plenty of water, both at the roots and over the foliage to keep it clean, long shoots are quickly made; the stronger and greener they are the more numerous and better will be the trusses of bloom.

Some persons attempt to cultivate Figs on back walls in the vinery, but with one exception I have never seen any that could be called successful. Enough of the sun's rays are not obtained to ripen the wood of the Fig trees, which need sufficient sun to produce a crop of fruit.—S.

MANNERS AND CUSTOMS—A CATALOGUE COMMENTARY. (Continued from page 140.)

HYBRID TEA ROSES.

THESE should be classed with the H.P.'s, according to N.R.S. rules, and rightly, for they are Hybrid Perpetuals, and, as we have seen, a good many of that class have probably some strain of the Tea Rose race in them. For instance, *Her Majesty* and *Lady Mary Fitzwilliam* are acknowledged to be crosses from the Teas, yet no one would think of reckoning them as anything but H.P.'s. But I think I have omitted two or three which are worthy of notice.

Cheshunt Hybrid (G. Paul, 1873) was the earliest of these crosses to be recognised as a Hybrid Tea; probably the races of *Victor Verdier* and *La France*, and certainly that of *Gloire de Dijon*, ought to have been added, if a new class was thus to be made. Of very vigorous (climbing or pillar) growth, and fine foliage, hardy and strong, not liable to mildew or to injury from rain. The blooms generally come fairly well and early, but they are not good enough for show, and are wanting in brightness of colour, and a dull Rose is surely a poor thing, however many good colours it may have.

Grace Darling (Bennett, 1884).—Sent out as a Tea, but pronounced to be H.T. by the National Rose Society. Some authorities, however, do not acquiesce in this judgment. Those who pronounced against it as a pure Tea were guided, I suppose, by the foliage, which certainly seems to indicate a cross; but so, at the same time, do the leaves of the *Gloire de Dijon* race, which, though more vigorous, appear to me very similar indeed. And when it is taken into consideration that *Gloire de Dijon*, by its strong growth, shows another departure from the pure Teas, which is not shared by *Grace Darling*, it seems inconsistent that the former should be admitted and the latter excluded. Of good growth for a pure Tea, not specially liable to mildew, or more injured by rain than most of the Teas, but it will not be seen to advantage except in dry weather. Rather wanting in stoutness of petal and fulness of centre, but comes well and opens readily. Of good shape and colour, and fair size, but not large enough to be shown among H.P.'s. Very free blooming and a good autumnal. Not a good laster, and requires good soil and generous treatment.

Reine Marie Henriette (Levet, 1878).—Of very strong climbing growth, with good foliage; not much liable to mildew or to injury from rain; very free flowering and a capital autumnal. Being brighter than *Cheshunt Hybrid*, this Rose has some claim to be considered the best of the climbers; but two of the three *Waltham* climbers (W. Paul, 1885) seedlings from *Gloire de Dijon*, of which No. 1 is the brightest and No. 3 the best shaped, are also well in the running.

NOISSETTES.

These are hardy, very strong growing, evergreen Roses, blooming in clusters. The flowers are naturally quite small, but almost all of them have been further crossed with the Tea race, which has the effect of much increasing the size and beauty of the blooms, but at the same time rendering the plants liable to injury from frost. All these Roses, and the pure Teas, require a rich, but not necessarily a strong or heavy soil, such as is most loved by the majority of the H.P.s. The true *Noisette* is itself said to be a hybrid between the Musk and Tea or China Roses; so that it seems rather difficult to decide as to what is a pure *Noisette*. Of those mentioned in the N.R.S. catalogue, *Aimée Vibert* (Vibert, 1828) with clusters of small white flowers, and *Ophirie* (which see) show less of the Tea cross than the others.

The true and Hybrid *Noisettes* have a characteristic custom, which is shared by the *Gloire de Dijon* race, of blooming from nearly all the buds of the long secondary shoots of the previous year, which should be left unpruned. Many of them will hardly bloom at all if closely pruned.

Caroline Kuster (Pernet, 1872).—This is a Hybrid *Noisette*, but for all practical purposes it might be classed among the Teas, to which it shows a strong affinity, as it is not of climbing growth, and will flower as freely as any Tea Rose if closely pruned, which other *Noisettes* will not. Of strong good growth for a pure Tea, with small foliage; not very liable to mildew, but, like all Teas, is injured by rain. The blooms sometimes come divided, especially the strongest ones, and they are deficient in colour, but good in petal, shape, fulness, lasting qualities, and size. This is a very accommodating Rose. A strong established plant in good soil may be used, either by very slight pruning and not thinning the buds; as a most useful bush to "cut and come again" at for serviceable pale yellow buds throughout the season; or, by severe pruning and rigorous disbudding, to produce a few show blooms of the first quality and the largest size, fully capable of being staged among our best H.P.'s. Free blooming and a good autumnal, does well as a dwarf, and for a Tea Rose fairly hardy.

Céline Forestier (Troillard or Leroy (?), 1858).—Of good growth, but not sufficiently lengthy to make a good climber. The wood and foliage are very distinct, the latter being evergreen and particularly bright and shining. Will sometimes bloom as a maiden or if closely pruned, which many of the *Noisettes* will not do. Not liable to mildew or much injured by rain. It blooms in large clusters, which should not be thinned, for no treatment can make a show Rose of it owing to the flat open shape, and the prettily coloured buds add much to the beauty of the truss. A free bloomer and fair autumnal; tolerably hardy, but liable to injury in severe frost; of pretty good constitution, and doing fairly on light soil.

Cloth of Gold (Coquereau, 1843).—Of very strong climbing growth for a south wall, liable to mildew, but can probably stand a shower. Here are manners, or rather the want of them, with a vengeance, for this Rose is unfavourably known as being by far the shyest bloomer we have, and though acknowledged to be an excellent bloom is not to be found in the N.R.S. catalogue at all. I once had a fine plant of it, which grew well in the sheltered angle of a south wall. Only once in eight years did it form a single bud, and that was after a very hot summer, during which the wood must have been not only ripened but almost roasted. About half a dozen buds came on that occasion, and as soon as they were clearly formed I stopped every other shoot and strengthened the blooms in every possible way, determined to see, even at the risk of the death of the plant, what this Rose is at its best. They were fine yellow flowers indeed, but it happened that I had also just at that time a large and splendid crop of *Maréchal Niel* on another south wall. I could detect but little difference between them either in shape or colour, even when closely compared, and came to the conclusion that this variety, with its absurdly shy manners, was not worth growing. It is said, however, by those who used to grow it twenty-five years ago that it bloomed freely and well at that time, but that it received a check in a certain severe winter which affected the constitution of the whole variety. This seems to be possible if we may judge from analogy, but perhaps jealousy was a hidden trait among its manners and customs, and that it "shut up" from envy at sight of the rising star of 1864, *Maréchal Niel*. It was stated, however, at the Rose Conference, and a photograph was shown to substantiate the evidence, that the *Cloth of Gold Noisette* flowers with great and long-continued freedom in Australia. That may be; in this country it certainly does not seem wise to waste time and space upon it. I heard some time ago, with respectful wonder, of an amateur who was about to grow the Teas and *Noisettes* on a large scale, and who ordered the different varieties by the hundred, and when it was added that among these were a hundred of *Cloth of Gold* the wonder increased, but the respect, I fear, diminished.

Lamarque (Maréchal, 1830).—This is a Rose which was highly prized thirty years ago, when good varieties were few. Of very strong climbing growth, bright but small foliage, not thoroughly evergreen. Little liable to mildew, but not liking rain. The blooms are large and effective, but open and flat, and not fit for show. Flowers very freely once, but the secondary bloom on a wall is very slight. The fragrance is very good and most distinct. I have never seen it grown except on a south wall, and it is hardy there against anything but exceptional frost.

L'Idéale (Nabonnand, 1887).—Too young to speak fully of, is not of climbing growth, and bids fair by its new combination of colours to become a successful rival of W. A. Richardson.

Maréchal Niel (Pradel, 1864).—Of very strong climbing growth, with magnificent evergreen foliage, very liable to mildew, and subject to injury from rain. The blooms come often divided or even quartered on a standard, much better on a south wall, but are apt to lose colour in the sun, and nearly always perfect under glass. A most splendid Rose, the best of this section and of all the yellows, and with strong claims to be called the Queen of all Roses. It is grand in petal, centre, shape, colour, lasting qualities, and size; a very free bloomer, and though on a south wall or under glass the second blooms are not numerous, it blooms freely as a standard throughout the season. Like all the Roses of this class the best blooms come on the long strong secondary shoots of the previous year, which should be left nearly of full length; but there is a good deal of the Tea race in *Maréchal Niel*, as shown by the strong characteristic scent, and by the fact that it will often bloom as a maiden, which many of the Noisettes will not do. A good authority even excludes it from the Noisettes, and classes it among the strong growing or Dijon Teas. It does not do well as a dwarf or on its own roots, and is decidedly tender, being liable to be injured or killed outright by sharp frosts. This variety is easily forced, and much grown for the market, the best method of training and pruning under glass to get a fine crop of these splendid blooms in early spring having been already described in the Journal. It may here be added that to ward off mildew we must not be afraid of keeping the ventilators entirely shut when there is any cold wind. This grand Rose has one piece of bad manners completely to itself—a liability to canker, especially at the juncture of stock and scion. Many remedies have been suggested for this, among which is the employment of Gloire de Dijon as a stock, which is said to suit very well. But there is no cure for canker, and it is best to attempt none. Good strong young plants are cheap, and soon come into bearing; but when putting in a new plant where a large Rose has stood, remember to take out a good deal of the old soil, and replace it with fresh rich stuff in which Roses have not been grown.—W. R. RAILLEM.

(To be continued.)

EUCHARIS AND BULB MITE.

I HAVE taken great interest in the articles that have appeared in *Journal of Horticulture* respecting the subject to which this heading refers. I also have been waging war against the same minute but numerous enemies with beneficial results. After reading Mr. Taylor's marvellous success, I feel constrained to say a few words on the subject. I think the same as your correspondent "M. D.," page 118, that Mr. Taylor having grown three partly decayed *Eucharis* bulbs to fill a 10-inch pot is no bad record for one year. I am surprised to see so many gardeners scout the idea that the bulb mite can be overcome and easily destroyed. Nevertheless it may, provided the operator can get at them with his insecticides, as I shall be able to show later on in this article. But it will not be accomplished by the method described by Mr. Henry Porter at page 140—viz., by washing them in warm water and by good cultivation. Good cultivation is quite out of the question if there is a mite left about the bulbs, for I find they increase at an enormous rate, and my experience teaches me it is impossible for the bulbs to make any headway, as the mites are very partial to the young roots, and quickly destroy them, causing the bulbs to lie dormant and eventually to die. Perhaps Mr. H. Porter will kindly state how he eradicated the mite from the centre of the bulbs by washing them in warm water, for it is essential that this be done before the good cultivation can effect a cure. When your correspondent says good cultivation, does he infer that we are all bad *Eucharis* growers? For I believe there are few collections that have not been troubled with this pest. I am inclined to think Mr. Porter's bulbs could not have been very badly infested with the mite, for had they been such as I was called upon to examine the other day they would have been dead, or at least in a worse state by now than when he washed them in warm water. It would have been impossible to get at the enemy by any other means than soaking them in some such liquid as petroleum or Fir-tree oil, the former being a sure destroyer of all insect life wherever it can be applied, but in no case should the bulbs remain in the mixture of petroleum more than one hour, or they would be destroyed.

The bulbs I mentioned above, which were so badly infested, were attacked, it appears, in the flower stem after being cut down, and had eaten their way into the inner part of the bulbs, and no washing could ever dislodge them. Then what is to be done? Destroy the bulbs as many advocate, or "bake, stew, or poison them?" My answer is, Neither; but carry out the following details, and success will follow, as I have proved in three collections of *Eucharises*, also with *Amaryllises*, *Vallotas*, with outdoor bulbs such as *Hyacinths*, *Tulips*, &c.

After shaking the bulbs from the soil wash them in a little clear water, so as to see the affected parts. Then if only infested on the outside, roll them in new slacked lime and soot, and allow them to remain in this condition for two or three days. After this, wash them in one gallon of water, to which add a quarter of a pint of petroleum and a good piece of soft soap, allowing them to remain in the same for a short time; but if the mite has penetrated the bulb make the wash stronger, and add a little of the fresh lime to the solution, allowing the bulbs to remain in it quite an hour. When potting them again, in all cases add a little lime and soot at the base of the bulbs. This I find essential, as it prevents the mite (should there be any left still alive) from settling at the base, and destroying the roots as they commence growing; and

with an occasional watering with soot and lime water the pest will be effectually destroyed, and the plants again brought to a state of perfect health.—ALFRED BISHOP.

THE BRITISH FRUIT GROWERS' ASSOCIATION.

A MEETING of the General Committee was held in the Horticultural Club room, Hotel Windsor, Victoria Street, S.W., on Wednesday, February, 19th, at 4 P.M., Mr. T. Francis Rivers in the chair, and there was good attendance of members. After the Honorary Secretary had read the minutes of the previous meeting, thirteen members were elected, and some additions were made to the Executive Committee. The place of meeting for the Committee during the year next came under consideration, and in accordance with a resolution passed on a previous occasion the Rev. H. H. D'Ombraïn had been written with the object of making some arrangements for holding the meetings at the Horticultural Club. A reply was now read in which it was stated that "the Committee gladly accedes to the proposal."

Letters were read from J. Storey, Esq., Town Clerk, Leicester; Mr. J. Burn, Abbey Park, Leicester; Mr. Henshaw Russell, Crystal Palace; Mr. E. Carpenter, Brighton, and Mr. W. Holmes, Hackney, with regard to the Conferences of 1890, and after some discussion, it was resolved that the Association should hold the following meetings to deal with the subjects named:—Friday, June 27th, Royal Aquarium, Westminster, Strawberries and bush fruits; Tuesday, August 5th, Leicester, general fruit culture for profit; Friday, September 5th, Crystal Palace, Plums and stone fruits; Thursday, September 11th, Brighton, general fruit culture, Grapes and Tomatoes; Wednesday, October 15th, Royal Aquarium, Apples. Offers of papers upon several subjects had already been received from members and friends of the Association, but the full programme will be announced later on.

It was resolved that the General and Executive Committee meetings be held in the Horticultural Club room at 5 P.M. on Thursdays, March 6th, April 3rd, May 1st, June 5th, July 24th, August 21st, October 2nd, November 27th, and December 18th.

Communications were read from provincial Societies with regard to providing lectures at their meetings, and the Secretary was directed to communicate with several experienced fruit growers on the subject.

Mr. T. W. Beach, Brentford, exhibited a sample lamp which he had employed for suspending amongst his fruit trees to catch the winter moth and other pests. It was an ordinary petroleum lamp, furnished with an extremely wide shade, the under surface of which is white, and is covered with a mixture of grease and tar. The moths fly to the light, and coming in contact with the shade are held securely by the adhesive mixture. A lamp of a similar kind has been tried on Lord Sudeley's estate with much success, and attention has been called to the subject in some provincial papers. Mr. Beach submitted a number of letters and clippings dealing with the matter, and was accorded a vote of thanks for his communication. Mr. T. F. Rivers referred to the loss the Association and the fruit interest had sustained by the death of Mr. Wildsmith, and it was resolved that a letter of condolence be sent to Mrs. Wildsmith.

TUBEROUS BEGONIAS.

At the February meeting of the Sheffield Floral and Horticultural Society a short paper on the above subject was read by Mr. W. Collier, who, at short notice, had taken the place of Mr. Herringshaw, who had been prevented by serious illness from attending and giving a paper on the same subject.

Mr. Collier said great improvements had taken place in the Tuberous Begonias. At one time we had plants that grew 2 or 3 feet high with small flowers, now we had larger flowers and dwarfier plants. Nearly every seedsman has his "celebrated strain" of Begonias. We are indebted to Messrs. Laing, Cannell, and many others for the great improvements that have been effected in this showy plant. The usual way of commencing to grow Begonias is by raising them from seed. If plants are wanted to bloom the same year, the seed must be sown early in January. By sowing then good sized bulbs are produced that will give a few flowers in the autumn. Prepare 6-inch pots, well drained, and fill them with some light soil, leaf mould, sand, and a little small peat, making the compost moderately firm, and sow the seed, which will be found to be very small, evenly on the top.

Slightly cover the seed with some sandy compost, and, after gently watering it, place glass over the pot, which should be plunged in a hotbed or in a propagating frame, and see that the soil never becomes dry. The seedlings will come up very freely, and as soon as they have made a small leaf or two carefully lift them out of the pot with a small stick and transplant into fresh soil and pots. Shade from sun, and they will soon grow freely. They may be grown in a hotbed outside, plunging the pots in ashes or cocoa-nut fibre, which will not necessitate so much watering. They will bloom a little the first year, but the great object is to raise a stock of tubers for the following spring. When growing them afterwards they should be started about the beginning of February. I keep the plants underneath the stage in the pots they bloomed in the previous year. Some people shake the tubers out, but I think that they keep better in the pots during the winter time, as the greenhouse stages are very large slates. In an ordinary greenhouse with lattice stages this plan would not do, as too much wet would reach the tubers.

As soon as the plants commence growing at the top shake them out. If you cannot get a good fibrous loam, have half loam to half peat, with leaf mould, charcoal, and a little sand. This will make a good compost. Start the tubers in small pots, only large enough to get the tubers in. If placed in a hotbed they will not require so much water, but a vinery is a good place to start them in, plunging the pots in a box and placing them on a shelf. After potting the tubers need very great care in watering, as if too much is given they will soon decay. They require much the same treatment as Gloxinias. As soon as roots are seen to push from the drainage it is time to place them into larger pots, for if not kept repotted they have a tendency to push up their flower spikes. At all times keep them near the glass. In summer they will do well in an ordinary greenhouse. If plenty of heat is not at command in spring do not start them before April, and give them the same treatment as Zonal Pelargoniums. If they are kept growing on they may be had of any size, but when they are root-bound they begin to flower. In this neighbourhood they do not succeed well outside, but in Lincolnshire they do. In a naturally light soil at Branston Hall they were planted similarly to Potatoes, and they grew and flowered remarkably well. Some people start them in pots and then plant out. When the plants are well established be careful not to give too much water. They may also be propagated from shoots with a little heel attached, and from cuttings of the tops of the shoots.

Discussion took place on the advisability of watering the soil in the pots before sowing the seed, which was recommended, and on the method of potting, Mr. Collier advising that the surface of the soil in the first potting should be the same in all subsequent pottings, not burying the tubers deeply. Mr. Collier was thanked for his paper.

GARDENERS OUT OF SITUATIONS.

WITH your correspondent, Mr. Bishop, page 160, I agree that a Gardeners' Self-Help Society is desirable, and I should be pleased to join any well matured project having that object in view; but at the same time the congested state of the supply of and demand for gardeners is not new, and in considering the matter it must be allowed that the disease is chronic, and should be remembered in assisting to choose the callings of our sons, to, if possible, lessen the supply. Although the evil is an old one, if a remedy can be found it should be tried. Mr. Bishop seems to think I am over the stile and out of the wood. Of course, that is a private and personal matter, but I trust I may never be out of sympathy with a brother in distress, and a gardener in particular. Such sympathy on my part would prevent me from withholding what I knew from personal experience to be true. And I likewise agree with the American motto, "Not to swap horses whilst crossing a stream." Further, not to drop the bone with a little meat on it offered by the nurserymen (which has kept many a good man from going wrong), at least not before the shadow of a Self-Help Society has become a substantial reality. Mr. Bishop seems to think a man should be able to dictate his terms of agreement and rate of pay when seeking temporary employment with a nurseryman, which I think under the circumstances most unreasonable. I consider to take the half loaf with a good grace betokens better manners. Whilst looking forward to being generous to our brethren of the craft in the future, let us not forget to be just to old friends of the past, or to despise the bridge that has carried many of the craft over. I hope that the day is not far distant when a system of national insurance for workers will be inaugurated on the same principle as that which recently has become law in the German empire.—R. M.

THE ACTION OF ROOT GROWTH.

[By Dr. G. M. Lowe.]

AT the last monthly meeting of the Lincolnshire Gardeners' Association, held at the School of Science, Lincoln, the Hon. Sec. (Mr. A. Wipf) read the following paper on "Root Growth," which had been prepared by Dr. G. M. Lowe, who was unfortunately unable to be present:—"There are three chief peculiarities about the action of roots, that, although well known, require to be kept in view in considering the subject:—First, their tendency to strike towards the centre of the earth (geotropism); secondly, their tendency to recede from light (apheliotropism); and thirdly, their extreme sensitiveness to contact. The action of gravitation need not be discussed, as it has been proved to have little or no influence on the root direction. Both Sachs and Darwin have demonstrated that root tips, like those of the growing shoots of plants and tendrils, continually move in a circular or spiral manner, searching their way, as it were, in every direction, but guided by the influences above described. If a Bean, for instance, be allowed to germinate on the surface of the ground, the young root (radicle), as soon as it protrudes from the seed coats, begins to circumnate, and is at once acted on by the force called geotropism, and bends down from whatever position it may be accidentally placed, towards the ground. Thus, if it be emitted on the upper surface of the seed, and its tip therefore is vertical, it cannot be acted on by gravitation, but, nevertheless, it curves over to one side and takes the shortest course downwards; it recedes also from the light, and, if other conditions are equal, will turn towards the shady side of the seed; and, further, if it meets with any obstacle, even though it be the thinnest possible tinfoil laid on damp sand, it will turn off at right angles and glide over it without leaving any impression. When the root tip reaches the soil surface it seeks to

penetrate it at some convenient spot, such as a minute crevice, a worm hole, or, if the soil be loose, between its particles. If the surface be dry and the Bean lying loosely, the latter will be raised up, as is often seen when large seeds are only lightly covered: but presently the root develops hairs in its surface and these attach themselves to irregular particles of soil, and so enable the growing root to force its way downwards; in this process the rotatory or zigzag movement of the advancing tips greatly assists.

"The apex of the growing root, it must be observed, is protected by the root cap, and when once firmly attached to the surrounding earth has a penetrating pressure (according to Darwin) of at least a quarter of a pound; but whilst thus increasing in length it increases also in thickness, pushing away the damp earth on all sides with a force equal to 8 lbs. The primary root also emits secondary ones, which are only slightly affected by geotropism, and so proceed sub-horizontally; their tips also rotate, and are sensitive to contact. These secondary rootlets again send out tertiary ones, which are not at all affected by geotropism, and so protrude in all directions, and thus the whole soil within reach is searched for nutriment. The aerial roots of the Pothos, or *Monstera deliciosa*, have afforded me excellent opportunities of observing some of these peculiarities. In this plant, which in its natural habitat grows over lagoons and tropical marshy localities, one thick and many smaller roots are thrown out opposite each leaf; the larger roots, which are about as thick as the little finger, grow rapidly downwards, and can be dealt with at will. Directly they strike damp soil they throw out numberless rootlets, and if they reach a tank of water will speedily take possession. If near a damp wall they incline at once towards it, and become attached to it in the same way as the root hairs of the Bean. This process is peculiar, and worthy of study. The damp surface seems to signify the outer envelope of the root stem, which then flattens itself against the surface and becomes glued as it were to it; the object seems to be to absorb water. Direction is also influenced by vapour, and again by contact, for if a card is placed on one side of the tip the latter recedes in the opposite direction. Again, if a pendent root be raised horizontally over the edge of any object, as a flower pot, the tip immediately curves downwards at an acute angle at the point of contact only. Light also acts on the principle before mentioned. I have been experimenting on these roots with a view to ascertain the action of various chemical substances on the colouring matters of the leaves, and endeavoured to receive the descending roots in tall glass vessels of fluid fully exposed to the light, but found that when the liquid was colourless the root refused to enter, no matter how tempting the contents might be from a plant food point of view, whilst a jar covered with black cloth, or filled with a strong solution of Judson's blue dye, was rapidly filled with rootlets."

A vote of thanks was tendered to Dr. G. M. Lowe for his paper.

GARDENING AT KEW.

I READ with much interest the excellent papers on Gardening in your last issue of the Journal (page 157). While agreeing in the main with Mr. Lewis's views there is still one point on which I think he is under a misapprehension. He says that the skilled workmen employed in the Royal Gardens, Kew, are to be regarded more as specialists than as gardeners proper. Now, that I consider is quite a fallacy. True, the departmental system is here in full operation, but the young men are by no means confined to one department. When they have become familiar with the details of cultivation of one class of plants they can on application be removed to another department, and have thus the opportunity of becoming practically acquainted with all the details of management of the largest collection of exotic plants in the world. Having only one class of plants under their charge at a time they are enabled to pay more attention to them than they otherwise could, and thus act on the good old rule of having "one thing at a time, and that done well." Further, a certain proportion of time is allowed the gardeners every week that they may go round the various departments and take notes, while there are also lectures on the sciences bearing directly on horticulture, so that they have a better chance of becoming good all-round gardeners than those in private places.

Mr. Lewis may not be aware of the fact that no gardener is admitted to Kew without at least five years' practical experience in good places. Having been employed in the Royal Gardens for some time, I can speak from personal experience. I hope you will find space for these lines, as the mistaken idea that the gardeners at Kew are specialists may be detrimental to the interest of the young men when they come to seek another situation.—R. G. K.

DRACÆNAS.—Plants of *gracilis*, *Goldiana* and *Lindenii* that have grown too tall may now have their heads rooted. These may with safety be cut off, and the heads rooted without losing a leaf if the pots can be plunged in a close frame in a temperature of 65°, and in bottom heat 10° higher. It is necessary to cut them where the wood is soft, as when cut where the wood is firm they are months before they root and often lose their foliage. This can be quickly tested by inserting a few eyes below where the head has been removed. These should be numbered 1, 2, 3, and so on as they are taken off downwards, and it will be found that the first below the head will form roots and commence to grow long before No. 3, and so on according to the firmness of the wood. It is a good plan to insert two or three eyes with a leaf attached from each plant after the removal of the top; it is a quicker

way of raising stock than waiting for the plants to produce side shoots. This appears the only reliable method of propagation with those named. Varieties of Cooperi, terminalis, and others that have had their stems thoroughly ripened, may be cut up into lengths of about 1 inch; if the stems are strong these may be split down the centre. These portions of stems must be sorted, placing those nearest the root in pans by themselves, for they invariably start into growth first. They may be laid amongst sandy soil that is in an intermediate state for moisture, and covered with half an inch of soil. The pans should be plunged, and the surface covered with cocoa-nut fibre refuse to prevent evaporation, and thus delay the necessity of giving water. If kept wet early in the season they are certain to decay.

PRIMULAS AT READING.

FEW plants generally employed for ornamental purposes alone have been so much improved and diversified in recent years as *Primula sinensis*—the Chinese Primrose, as some prefer to term it. The usefulness of the plant has assisted greatly in extending its popularity, and it now takes a foremost place amongst those most prized for winter flowering. Though requiring care it is not by any means difficult to grow, or to grow well, and it is not surprising therefore that seedsmen recognising the potentialities of the plant have given it a large share of attention with correspondingly favourable results.

During the past two months Messrs. Sutton & Sons, Reading, have had a display of Primulas in their nursery most creditable to the firm, and representing in an interesting manner the progress that has been made within the past ten or twelve years. Ever since the Chinese *Primula* began to be appreciated as a garden plant Messrs. Sutton and Sons have given it their close attention, and they may fairly claim to have contributed in no small degree to its present popularity. In 1879 the firm obtained a first class certificate from the Royal Horticultural Society for a variety distinguished by the richness of its colour, and named Ruby King. This was the forerunner of a series of fine varieties; and though the one named is still unsurpassed in its class, an astonishing diversity in shades of colour, form, or size of flower, habit, &c., has been introduced, and numbers of certificates have been awarded to the types thus formed. An admirable example is furnished of what can be effected by continued well-directed efforts, and it also shows that capital, labour, and intelligence are indispensable in producing such results. The beautiful display of bright or soft-tinted Primulas indicates the accomplishment of a great task, and a reference to what may be termed the "stud book" shows the manner in which it has been effected. These records of skill in experimental crossing are unique, and it is easy by their means to trace back the parentage of any variety for ten or twelve years. This was actually done for my edification in the case of one variety, and proved how carefully the system had been devised and followed, for the lineage was traced most readily, each parent in every generation being given.

It would be unnecessary to refer in detail to the many varieties, they are so accurately and fully described in the catalogue that it would be superfluous, but a few notes will suffice to indicate the lines upon which most of the improvements have been effected. First as regards the flowers, we find that they have been much increased in size, the substance improved, and consequently their duration prolonged; the form has also been rendered more symmetrical and less "starry" than was the case with the earlier varieties. The colours have been diversified, and it is here that the advance has been made, for from pure white, through blush, rose, red, crimson, and purple to blue, the tints are innumerable, and all that is wanting is a yellow variety, and there is a prospect that this may be secured at some time. Of course there is a repetition of nearly all the colours secured in double flowered varieties, many of which are most useful for cutting.

In habit and foliage much has also been done to increase the variations from the original type. The plants are now strong and compact, the leafstalks relatively short, the flower trusses being borne well above the foliage, but not sufficiently so to give them a drawn appearance. The foliage imparts much character to the plants, and the two broad classes of varieties are those with fern leaves, and those with round or plain leaves, but to these can be added the varieties with leaves crisped and curled at the margin, while other classes are being formed, one with leaves of an extremely dark metallic appearance.

Attention has been given in the past few years to a prolongation of the season of flowering, not only by successional seed sowing but by raising varieties that have a marked tendency to flower either early or late. Much success has attended these efforts, and several have been fixed that assist materially in this direction. Plants of the perpetual varieties raised from seed sown at the same time and treated in every way identically have shown a difference of six weeks to two months in their flowering periods.—VISITOR.

MAQUI BERRIES.

THE Maqui is a small evergreen tree or shrub (*Aristotelia Maqui*) common in Chili along the course of torrents and in shady, mountainous woods. It belongs to the Linden order (*Tiliaceæ*), which abounds in species, the inner bark or bast of which affords fibre of more or less value. The most important are jute and the linden from which the well-known Russia matting is made. The Maqui also affords a fibre which is used in Chili for cordage. It is easily cultivated in gardens

in the south of England, and at Kew grows vigorously with the protection of a wall. Whether its cultivation for the production of fibre would pay is doubtful, looking at the profusion of excellent fibre plants which are not woody which are now known. In Chili the fruits of the Maqui are eaten either fresh or preserved in different ways. Mixed with Grapes, a wine is also made from them. The shrub varies with either dark purple or greenish white berries; the latter are preferred in Chili.

A curious industry has sprung up of late years in the collection and export to Europe of the berries for colouring wine. For the particulars contained in the following letter Kew is indebted to the Consul-General for Chili. The Maqui flowers freely at Kew, but rarely fruits. Its cultivation for the sake of the berries would, therefore, be precarious in England, but would probably present no difficulty in Southern Europe. The first notice of the introduction of Maqui berries into Europe is apparently that given by J. Poisson in the "Revue Horticole" for 1886, page 467. He suspected that they were intended for the colouration of wine, a purpose for which he stated that Elder berries were already employed in France. He explains that the object of adding the berries to Grapes in making wine in Chili was for the sake of the colour. No doubt it occurred to some ingenious person to extend their use in a dried state for the same purpose to the Old World.

The following letter was sent by Senor Juan de la C. Cerda, Consul-General for Chili, to the Royal Gardens, Kew:—"In reply to your kind letter of the 14th inst., I am sorry to inform you that I do not know where you could get some fruits for your museum of the *Aristotelia Maqui*; but I am writing to my friends in Liverpool and Glasgow, and as soon as I have any information I will let you know. Probably I may get some fruit, and if I do I will be very pleased to hand it to you. The common name of this fruit in Chili is Maqui, the same as the plant, and it is cropped from the wild shrub in the forests. It is not cultivated at all. I think that the attention of farmers will be very soon drawn to the cultivation of this important plant, in consideration of the great development in the exportation of its fruit to Europe in the last three or four years for colouring wines.

"The total of this exportation was 26,592 kilos, worth 2234 dols., in 1884; 136,026 kilos, worth 10,882 dols., in 1886; and 431,392 kilos, worth 34,515 dols., in 1887; of which the exportation to France was 500 kilos in 1884, 115,000 in 1886, and 315,774 in 1887. I have no statistics for 1888 and 1889, but it is to be supposed that the increase may have been in the same proportion. Wine is not produced from this plant, but ribbons from the stems for fastening in farming purposes are usual, and easily made without any preparation, simply by hand.

"I think it would be a benefit for Chili as well as for England, where this shrub grows in the open air, to carry out an experiment with two or three small stems of the good specimen you have in the Gardens by passing the ribbons of these stems produced by hand through any scutching machine, in order to ascertain the value of its fibres for textile purposes."—(*Kew Bulletin*).

FRUIT FORCING.

PINES.—*Plants Starting into Fruit.*—Plants selected about the beginning of last December, and started by an advanced temperature and increased moisture, are now showing fruit, and as it is advisable to promote the ripening as much as possible, the temperature may be maintained at 65° to 70° at night, and 75° to 80° under favourable circumstances, ventilating at 80°, allowing an advance to 85°, utilising the sun heat as much as possible. With the fruit advancing the plants will require more water at the roots; examine the whole stock once a week, as with increased light and heat the need for water will correspondingly increase. Recently started plants to succeed those already named should have a night temperature of 65°, and 70° by day artificially, which will be sufficient for them some time longer.

Starting Suckers.—Suckers will have to be started about the commencement of March to provide plants to give a succession of fruit from next December onwards: therefore attend to the preparation of soil for potting, and a fermenting bed in some close structure to generate and maintain a bottom heat of 85° to 90° near the surface, and with means of maintaining a temperature of 55° to 65° by fire heat with regularity.

VINES.—*Early Vines in Pots.*—These must not sustain any check through dryness. Top-dress with rich turfy loam and decayed manure in about equal parts, placing rims of zinc 3 or 4 inches deep round the tops of the pots, or if the pots are plunged to the rim in fermenting material, strips of turf of about that thickness should be laid so as to form the necessary dish. In order to encourage the swelling of the berries keep the laterals below the bunches somewhat closely stopped, allowing more liberty to those above them, but avoid overcrowding the trellis with foliage that cannot have full exposure to light. With the Grapes approaching the stoning process careful treatment is necessary. Ventilate early in the day, affording a little air at 70°, increasing it with the sun heat to 85°, closing at 80°, and if an advance follow to 85° or 90° all the better. Avoid cold draughts, they are a prolific cause of

"rust." If red spider appear, paint the return pipes with sulphur lightly. An overdose may injuriously affect the skin of the berries and spoil the crop. Afford liquid manure a few degrees warmer than the house in which they are growing, applying it also to the turf placed around the rim of the pots, as also the plunging material where the roots are allowed to find their way from the bottom of the pots, there being nothing like plenty of feeders to secure well-swelled berries.

Early Forced Planted out Vines.—Vines started early in December must have the berries thinned, and lose no time in doing so as soon as it can be seen which are properly fertilised by their taking the lead. Endeavour to have compact bunches, tying up the shoulders in preference to taking out a quantity of berries. Remove superfluous growths and particularly superfluous bunches unflinchingly, seeking a full crop of well finished bunches, duly furnished, properly swelled, and perfect in colour, which are much more creditable than an enormous crop of red berries, as sometimes seen. Allow the laterals to extend beyond the fruit as far as is consistent with the exposure of the foliage to light and air, tying and stopping as required. Afford a thorough supply of tepid liquid manure to the inside border at intervals as required to maintain the soil in a thoroughly moist state, and mulch with a couple of inches thickness of short manure, and as fresh as is safe, for although a moderate amount of ammonia is beneficial, when too powerful it is productive of serious injury. Let the night temperature range from 60° to 65°, 70° to 75° by day, with 10° to 15° advance from sun heat, commencing to ventilate from 70°, closing between 80° and 85°, damping all available surfaces well at the time. Do not syringe the foliage, as, however clear and soft the water may be, there is danger of sediment—a deposit on the berries, and though it may escape observation until the Grapes begin finishing, it is certain to then appear as a serious blemish. The outside border must be well protected against the chilling effect of snow and cold rains.

Vines Started at the New Year.—Disbud the Vines now the best shows can be determined, and it is not wise to be in too great a hurry about this work, nor in tying the shoots to the trellis, which must be done carefully, so as not to detach the shoot at its base, nor cause it to snap by bringing it down too sharply at the point. Remember also that the object of dishudding is to give the growths full exposure to light, it being better to err on the side of too little rather than too much, or overcrowding the foliage. Stopping too should not be done too hurriedly. Allow at least two, and if possible three or four joints beyond the bunch, and stop all laterals below the bunch at the first joint, or they may be rubbed off except from the two lowermost leaves. The laterals from these should be pinched at the first joint, but those level with and above the fruit may be allowed to extend as space admits. When in flower afford a night temperature of 65° to 70°, with 10° to 15° rise from sun heat, closing at 80°. Vine flowers set best when the atmospheric moisture is not excessive. An over-moist or a dry atmosphere must be equally avoided. Muscats require a somewhat higher temperature and drier atmosphere than Black Hamburgs when setting, artificial impregnation being practised with all shy setting varieties, particularly Muscats, which are often deficient of pollen, or if plentiful a better set is secured by fertilising every bunch carefully with Black Hamburg pollen than when their own is employed. Keep the points of the bunches of Muscats well up to the light.

Late Vines.—A long season of growth is required by late Vines, as to insure the Grapes keeping well they should be fully ripe by the middle or end of September. To effect this start the Vines at the end of February or the beginning of March. Let the inside border be well supplied with water at a temperature of 85° to 90°, and if there are fermenting materials at command a bed may be made upon the border, which will lessen the necessity for fire heat and insure a regular break. The rods should be sprinkled two or three times a day, maintaining a night temperature of 50° to 55°, and 65° in the daytime, by which means the Vines will start freely, and there will be every chance of the Grapes becoming thoroughly ripe by September, even such varieties as Gros Colman, the most noble late Grape, and Gros Guillaume, which require a month or six weeks more time to ripen thoroughly than Lady Downe's and others. As a general rule all houses of late Grapes must be started not later than the end of next month, hence they should be prepared as soon as possible, washing the woodwork, dressing the Vines, removing the loose surface soil from the border and supplying with fresh, to which has been added some fertilising agent, great benefit being derived from judicious applications of artificial manures, and having tried most of those advertised and found all good, and in most instances they are preferable to bones, as these in the crushed and half-inch state are slow in action, and they are particularly valuable where heavy mulching of stable and farmyard manure, which have a tendency to leave a deposit of soapy matter behind, have been employed by the mineral matter supplied in an available form. The outside border, which is a necessity of late houses in order to the Grapes keeping plump, should be protected against chill from falls of snow or heavy rains and frost. A moderate covering only will be necessary.

Late Houses of Black Hamburgs.—Keep the houses cool and dry, not allowing the border to become dust dry and crack, but a moderate amount of moisture only will be necessary to preserve the roots in sound condition. The only precaution necessary is to ventilate fully at and above 50°, and when that becomes the mean of the external air, or a little before, the Vines will break naturally, which usually takes place during April. The only assistance necessary is to maintain an artificial temperature of 50° to 55° at night and on dull days. The Vines will set their crops by the early part of June, and swell them

with sun heat, artificial heat only being required after the Grapes begin to colour, as they are much improved in quality through ripening in a higher temperature; indeed the Grapes must be thoroughly ripened or they will not keep well.

Vines from Eyes.—Those inserted as advised have rooted, and if in small pots should be shifted into larger as soon as the roots reach the sides, standing the pots on shelves over hot-water pipes in preference to plunging them in bottom heat; or if the eyes were inserted in pots or pans, several together, they may be placed in small pots singly, plunged in bottom heat to insure speedy root action, and when the roots reach the sides transfer them to 6-inch pots. Syringe well amongst them, and stop those intended for fruiting at the first joint of the laterals, but those intended for planting out this season, whether grown in pots or turves, may be allowed to retain all the growth made.

TOMATOES.—Early supplies are best grown in pots. For first crops cuttings struck in autumn and kept in small pots near the glass in a house with a minimum temperature of 50°, affording no more water than to prevent severe flagging may, early in January, be transferred to 10-inch pots, draining well and placing a few rough pieces of turf over the crocks, turning out the plants on those, using rough turf with about a fourth of well-decomposed manure, mixed for filling up around the balls. A considerable portion of stem, if the plants are tall, being buried by coiling it round the inside of the pots carefully, and bring the growing point to the centre, supporting with a neat small stake sufficiently long to reach the trellis. There is considerable space left in the pots after the plants are put in, which is utilised afterwards for additions of compost as the plants advance and the roots protrude. They are supplied with surface dressings of artificials after they become established. The plants are stood at the sides of a low span-roofed house, kept at a temperature of 60° to 65° at night and 70° to 75° by day, and are trained to the trellis fixed about 9 inches from the glass. The plants show trusses of bloom when only a few inches above the rim of the pots, and at about every second joint right away, they being trained as single cordons, kept to one stem by rubbing off all growths except the lead. In that way they go to the extent of about 6 feet up the roof, when all growths are removed as they show, and the foliage is kept comparatively thin by shortening the leaves gradually, the terminal leaflet being pinched off when the leaf is quite young, and the leaf is reduced about a third or not more than half when the truss of fruit corresponding to it is set and swelling. The first or cutting plants have now fruit set and swelling. The flowers as they become fully expanded, should be carefully fertilised, distributing the pollen gently with a camel's-hair brush; a slight sharp rap of the footstalk of the truss is also a ready means of distributing the pollen. Properly fertilised flowers invariably afford the best shaped and fullest crop of fruit. Ripe fruit will be had during April. To follow these plants we have others from seed sown at the new year. These are grown on shelves as close to the glass as they can well be kept for safety, the object being to get them hard, the growth thoroughly solidified as well as sturdy. They are transferred to pots 10 or 12 inches in diameter, not later than early March, and they afford fruit from May onwards. For planting in houses that have been used for hedging plants, Tomatoes are raised from seed sown early in February, and strong plants showing bloom, are fit to plant out in April, or not later than middle May, if they are to afford a profitable crop. In this way plants for cool houses are raised, getting them strong and well established and hardened off in 6-inch pots, the chief point being to get the growth firm from the beginning, to insure which they must be kept well up to the light. The kinds are numerous, each grower having his special favourite. Ours are Acme and Hackwood Park, with Ham Green Favourite to fill the basket. Planting out is best for affording general summer and autumn supplies of fruit.

KITCHEN GARDEN.

POTATOES.—Those in frames are making rapid progress. They have been supplied lately with water heated to 90°, but as they are on rather moist hotbeds they do not require this very often. Air is admitted almost daily from the opposite side to that from which the wind is blowing, and this keeps them sturdy and healthy. They are covered with mats nightly, but these are not applied until 6 p.m., and when not frosty they are removed at daylight. We find the crop much better when treated in this way than when coddled. Tubers of early sorts placed on their ends in shallow boxes and in a vinery to sprout a fortnight or three weeks ago are now in good order for planting, and after remaining in a cold frame for a few days they will be planted along the bottom of a south wall and on a south border in a sheltered position. These are the only situations in which Potatoes can be planted with advantage or success during March. Continue to spread out more early and second early tubers intended for planting in a few weeks hence, and let them form shoots without being drawn up weakly or delicate in colour.

RADISHES.—This is the first salad plant that can be raised in the open air, and those who are deficient of forcing space and cannot grow them under glass may now sow a pinch of seed in the most sheltered spot they can find in the open. Two or three rows a yard or so in length will be sufficient for the first sowing, but they may be sown three times during March.

JERUSALEM ARTICHOKE.—We fear this most useful winter vegetable is not grown in every garden. It generally finds a corner in large establishments, but rarely in that of the amateur or with the cottager. It is looked on as unfit for the table unless prepared by the hands of a

professional cook, but those who have ventured to try it as a common winter vegetable have been more than satisfied with its excellency and usefulness, and we recommend it to all as one of the best winter crops that can be grown in any garden. It produces tubers almost as large as Potatoes, but it is in no way liable to disease, will bear heavily in soil where the Potato would fail, is never injured by frost in spring, nor does it require protection in winter. They are left in the ground and dug as required until this time, but as they should be dug and replanted every spring the time has arrived for this operation. They grow in clusters, and if allowed to remain over a second season they would become a mass of small growths and small tubers. Dig the whole, clear them all from the soil, select a number of the best formed tubers for subsequent planting, and store the others under ashes for further use. Spread a quantity of manure on the surface of the ground intended for their reception, begin to dig it, and as this goes on plant a row of the roots every 2½ feet. Keep the sets 1 foot apart, and place them 3 inches below the surface. Their stems are stout and hardy, are not easily injured by wind, and attain a height of from 7 to 10 feet, forming a serviceable screen or shelter.

VEGETABLE MARROWS.—These are not valued much as a vegetable in the autumn, but if they can be secured in May, June, or July they are greatly valued, and all who can do so should sow a few seeds at once to secure a few early plants which if treated like frame Cucumbers, will fruit in May. If planted on a bed under a frame at first, the latter can be removed when the summer comes, and the same plants will continue to bear for months if the fruits are regularly cut off as they gain a useable size.

CELERY.—All who require Celery in July or August for exhibition or other purposes, should sow a pinch of seed without delay. The main or winter crop need not be sown until April, and where only ordinary Celery is needed we advise delaying sowing till then. A pinch of seed placed into a 6-inch pot will produce many scores of plants. It will germinate, and the plants grow freely in a temperature of 65°. Old Celery is lasting well this winter. We have many rows still almost in as good condition as when it was earthed for the last time in November. Some may have to dig the remainder of their crop to get the use of the ground it is on, but it keeps in very much better condition until late in the spring if left undisturbed in the trenches than when dug and stored anywhere else. We have sometimes used every alternate trench at this season, dug the ground, and sown a row of Peas, and this allows ground to be cropped, while the Celery between the Peas is not in the way, and may be left as long as it lasts good.

YOUNG VEGETABLES UNDER GLASS.—Cauliflowers, Lettuces, Brussels Sprouts, and other young vegetables under glass are now growing rapidly. If they are kept in a close high temperature far from the light they will be spoiled, but if near the light, given all the air possible without checking them, and never allowed to form long spindly stems, they will all prove highly useful. If they have been raised in boxes or pots, try and move them from these as soon as they are 3 inches high. They may be returned to boxes again, but the better way is to make up a shallow hotbed, place any old frame on the top of it, put some good soil inside, make it very firm, and dibble the young plants in 3 inches apart. By careful nursing for a few days and ordinary care afterwards, these may be turned out into the open quarters in the end of March or early in April with great success. This is the best of all ways of treating young vegetables of all descriptions, and it is entirely due to this that we secure many fine extra early crops.

SPRING ONIONS.—This is a common term applied to all Onions sown in spring. The crop is one of the most important of all, as on it depends a good or bad supply of Onions during next winter. The ground selected for the spring Onion crop should be a strong rich soil fully exposed to the sun and guaranteed to keep free from worms or grub for the next seven months. This can be insured by selecting a piece of ground that is not maggoty and dressing it while the manure is being applied with a large quantity of soot, a small quantity of gas lime, or a little ordinary lime, but the former is better applied in the autumn. Dig the soil deeply first, then fork it and break it well, and on the first fine dry day after March is in open drills all over the piece at a distance of 10 inches or 1 foot, and 2 inches deep. Sow the seed evenly but thinly, cover with the rake, tread the soil over the seed, rake all smooth, and success is sure to follow. As to varieties to sow now the Fanbury is a reliable sort, and James' Keeping should always be included, as it is the best of all for use the following spring after it has been stored in the autumn. It is not a large growing variety, but its long keeping qualities make it invaluable.

THE BEE-KEEPER.

QUEEN BREEDING—PUNIC BEES.

In the Journal for January 30th "A Lanarkshire Bee-keeper" appears to slightly misunderstand me. Let me assure him that I did not intend in the slightest degree to construe his remarks into a condemnation of my plan of rearing queens, and I very much regret that he should have been led to think I meant so.

I understood him to put the matter in this way. "Yes,

'A. H. B. K.,' the queens you rear in the way you direct are bound to be good ones, if it is possible to rear a good queen, and bee-keepers who practise the method are sure to be gainers; but I do not admit that the progeny of such queens will hibernate, nor do I admit that queens reared in nuclei will turn out worthless, as I have for many years divided up stocks into nuclei with queen cells, and such queens have always been satisfactory." Of course these are not his exact words, but are what I understand him to mean. I do not doubt or question his assertion that his queens were always satisfactory, because, being an old practical hand, and having noted that when cells are chilled or retarded in hatching, the queens hatched out with wings or legs deformed, he would be sure to guard against the cells being chilled. Here, again, is a difference between his plan and what has been the practice or advice of noted queen breeders. He reared his queens in full strong stocks, and then divided them, just as the queens were ready to hatch. Others have nuclei ready—just a handful of bees—and though they rear the cells in full stocks they cut them out as soon as sealed and give them to nuclei, or hatch them in nurseries, and then set the stock to rear fresh cells, so that before the first cells hatch there are others sealed and cut out. It is this practice that I condemn, and which I assert can never result in any but a worthless queen.

In practical hands the plan described by "A. L. B. K." will turn out "satisfactory" queens—that is, queens that will satisfy anyone who has never seen any better; but I am one of those who are never satisfied, and having found out how to breed better queens with less risk of getting faulty ones, I prefer to use and recommend it in preference to any other.

Supposing, for argument, I drop the question of "hibernation." The fact remains that queens reared in the manner I have laid down will, after the third generation, produce bees that will never have winter dysentery or abdominal distension, or even spring dwindle. Whether it is because they hibernate, have stronger constitutions, or eat less food, or what not, this fact remains, and of which I am positive.

I have also shown that while I condemn cell cutting out, queen nurseries, and all other means of hatching queens, I can rear more queens with less trouble on my new plan than any person has ever been able to do by any other means, no matter how carried out. What do all these authorities on queen rearing say about my system of rearing a daily or weekly supply of queens from one stock all the season without cutting or losing a cell? Who knew that when bees were under the swarming fever they would rear and seal fresh queen cells while had they ever the opportunity to prevent such queens from killing each other as long as the swarming fever was on them? There has been no end of talk about getting queens reared from the egg and all kinds of dodges to accomplish it, but in my plan all that is necessary is to give the bees a comb with some eggs in, and queen's cells will be started at once on such eggs, even if they are drone eggs, and this, with queen cells sealed or unsealed, or queens piping in their cells, or already hatched.

Our friend says the Punic bees I sent him do not appear to be hibernating. In my case, since I wrote last, they have shown signs of activity consequent on the very warm weather we have been having, and if his report of weather and temperature is worth anything, his locality, though 200 miles further north, is considerably warmer than it is here, hence his bees may be in quite an active state. I do not imagine that bees of any kind will hibernate when warm weather sets in, or after they have been induced to commence breeding. Punic bees, again, are more active than any others, beginning work in the summer before sunrise, and working on days that are too cold for any other race to venture out. Again, these bees in their native land never do hibernate. They come from North Africa, near the great Sahara desert, where everything is dried and burnt up in summer. The rains fall in November, which speedily starts everything growing. In December the flowers expand, from which time onwards until May

they find plenty of forage. January and February are the main swarming months. After the hot weather sets in they get no honey at all, and have to extract sweets from ripe and bruised Dates and other substances that yield saccharine matter, which they would find the best to collect early in the morning before the sun is high, and while the dew was on, but as the sun in those parts is soon high above the earth, the bees to get every advantage would leave their hives at the first glimmer of day; at least, this is how I account for their having this peculiarity. They also have the power to eat hard dry crystallised sugar even when the crystals are upwards of a quarter of an inch square. The first time I noted them doing this was after I had left some feeders in which the syrup had slowly crystallised at the bottom in an empty hive. The Punic bees found them and cleared every particle of sugar out. No other bees touched it. I have since found that they can take a hard dry sugarloaf almost as readily as syrup.

I have expressed myself previously as being of opinion that these bees would not prove as good as others for comb honey, especially Carniolians, on account of their lavish use of propolis. I have had to alter my opinion on this point, as last season they filled and sealed glass sections very much better, more evenly, and with whiter cappings than any other race. There was a great difference between our native blacks and the work they turned out.

I have now come to the conclusion that they are the best race of bees ever introduced to this country. They have entirely won my esteem, as I was quite prejudiced against them at first, being fully sure that bees from the tropics, where winters are equal to our springs and early summer, would never winter in this country. I now give them first place on every point except beauty. They are blacker and not nearly so good looking as our common black bees, but "Handsome is that handsome does," at least that is the opinion of—A HALLAMSHIRE BEE-KEEPER.

SINGLE CASED HIVES.

WOULD "A Lanarkshire Bee-keeper" kindly state if his hives are single-cased all round, how thick they are, and what influence the sun has on them in summer time? Do they need protection from it? I should like to make some for this season, if "A. L. B. K." would state the measurement, the number of bars required, or help me in any way.—YORKSHIRE.

[The majority of the hives I possess are single cased. Double cased or thick sided hives are a great mistake if they are to be moved about. Single cased hives require outside protection, and there is nothing better than long grass well dried. A uniform degree of heat at all times is desirable, and during summer archangel mats do well, as they shade the hive and allow evaporation to pass away. It is not so much the direct heat from the sun that causes combs to collapse as the heat from the bees through defectively constructed hives. I have had combs collapse several times in double cased hives, but never in single cased ones. Five-eighths of an inch is thick enough for any hive walls, being strong enough for every purpose. Less thick would not be sufficient for fastenings and handles, while thicker is too weighty, and the wood holds damp.

Our contemporaries advise uncovering supers during hot weather—a mistake. Keep supers always well covered, and the sides of the hive as well. The bottom ventilation is the safety valve during excessive heat.

As the sluggard has been told "to go to the ant," so do I advise the beginner to go to the bee and study her ways. One thing in this respect, I have never seen her depart from fixing her combs at less than $1\frac{1}{2}$ inch from centre to centre. My hives are exactly 14 inches wide inside measurement. It is immaterial whether that distance be strictly adhered to, but the nearer the square the better.

That distance admits nine frames with an additional quarter inch next the sides for obvious reasons. A mouth piece half an inch high the whole width of the hive should be in all the divisions. It is formed slide and groove in front of the hive by a pair of five-eighths match ploughs. The rebates for bars half an inch deep and quarter inch wide is easy work for an amateur if he uses a drawer bottom plane. This tool of a special make grooves the bars for foundation. The front and back to receive the sides are best done with a saw, and should project over the sides nearly a quarter of

an inch and rounded. This gives a neater appearance than when flush, and is easier made. If the above is not sufficient help, further queries will be answered.—A LANARKSHIRE BEE-KEEPER.]

TRADE CATALOGUES RECEIVED.

Eric F. Such, Maidenhead.—*Spring Catalogue and Amateurs' Cultural Guide, 1890.*

Messrs. Pitcher & Manda, Short Hills, New Jersey.—*Catalogues of Chrysanthemums, Single Dahlias, and Orchids.*

M. Campbell, Blantyre.—*Catalogue of Florists' Flowers.*

Dicksons, Chester.—*Select Farm Seeds.*

Dicksons & Co., Edinburgh.—*Farm Seeds.*

T. S. Ware, Hale Farm Nurseries, Tottenham.—*Catalogue of Choice Hardy Perennials, Hardy Climbers, Paeonies, Florists' Flowers, Dahlias, &c.*

B. R. Davis, Ycovil.—*List of Begonias.*

* * * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Books (Hopeful).—The following will afford you much information:—Dr. Masters' edition of Hefrey's "Course of Botany" (Van Voorst), and Johnston and Cameron's "Elements of Agricultural Chemistry," Blackwood. They can be obtained through a bookseller. You may write to F. W. Burbidge, Esq., Trinity College Botanic Gardens, Dublin (who prepared a work on drawing), enclosing a stamped directed envelope for reply. There are many young men with "great aspirations," but only a few of them become "great gardeners." Close study and hard work are essential to success.

Tulipiana (D.).—Please state the nature of the information you require in reference to the treatise.

Sheep's Manure for Mushroom Bed (R. C. W.).—When somewhat dry, but not too dry, it is excellent for mixing with manure from horse stables for the purpose in question.

Rose (J. H. V.).—As the reference is to matter in the "Rosarians' Year Book," you had better write to the Rev. H. H. D'Ombraim, Westwell Vicarage, Ashford, Kent, enclosing a directed postcard for his reply.

Articles on Gardening (F. P.).—You regard the matter on which you write just as a sensible practical man must of necessity do. Good matter cannot be too widely circulated, and on that principle we endeavour to act; and we suspect you could add to the usefulness of the pages which have been useful to yourself during the past ten years. Short notes are often even more acceptable than lengthy articles. The *Chrysanthemum Annual* is in the press and will shortly be ready for distribution.

Manure from Cow Shed (Amateur).—This is better than manure from horse stables for dry gravelly soil, because of its cool and moisture-holding nature. Its value depends largely on the food consumed by the animals. If these are lean, young, or in milk, the manure will not contain much substantial food for crops, and a peck each of kainit and bone meal to a load would add considerably to its value. In addition to digging manure into the ground, heavy mulchings—that is, placing manure on the surface of the ground—is good for dry soils.

Pruning Young Apple Trees—Rhubarb (Golden Spire).—We think we understand your case now, but it would have been better if you had stated about the length of the shoots. You will not err, however, by cutting entirely out any of a weak wiry looking nature, shortening the longer and stronger about half their length, or more, to buds pointing outwards as the growths extend in the direction in which the buds point, and overcrowding should always be avoided. We should certainly object to "planting all the ground" with Rhubarb. In some of the London market gardens rows of Rhubarb are grown between the rows of fruit trees, and the ground being highly manured.

the plan answers very well. We do not advise your planting Rhubarb within 8 or 9 feet from the stems of the trees.

Land for Fruit Growing (D. D.).—Fruit is well grown in some parts of Essex, and near Colchester. The best land is such as will grow the best Clover. It must be free from stagnant water and well worked to a depth of 18 inches or thereabouts, not, however, bringing the sub-soil to the surface. Given such land, the question of profit depends on the cultivator. Some persons make a "comfortable living" by fruit culture, and others fail. Mr. Robert Garrod, who is well known in Colchester, has found the occupation satisfactory, and made his land at the least twice as profitable as that surrounding his enclosure. You cannot do better than consult him on the spot.

Gardeners Out of Situations (A. B. D.).—Your letter is very well written, and we see no reason why you should hesitate to send contributions to the press on subjects of practical gardening with which you are acquainted, but it would be useless our publishing the suggestion which is the purport of your communication. It would simply divert attention from the main subject, and have no useful results. As you may see on page 160 of our last issue, there appears to be a Society in existence for affording aid to unemployed gardeners, and if the rules are sent to us we will consider the advisability of making this Society more widely known. It is scarcely necessary to say that we should only be too glad to give encouragement to any organisation established on sound lines that would be of substantial benefit to the gardening community.

Vine Eyes Falling (J. M. H.).—As you followed Mr. Barron's instruction it would, perhaps, have been better to have written to him. The elongation of growth is the result of heat and moisture, and the stoppage of that growth the consequence of the absence of roots. The elongation continued till the sap in the wood was exhausted, and by that time, or before, roots ought to have formed. Either the wood was not as it should be, the soil unsuitable, or the top heat too great. You will observe the stress which the author of "Vines and Vine Culture" lays on the necessity of early well-ripened wood for propagation. He is quite right, and we suspect the portions you selected were faulty, and not well stored with starchy matter. Try again, with the best wood you can find, not small, hard, exhausted wood, but firm, well fed wood. Insert the eyes in pure turfy loam, crushed charcoal and sand, plunging the pots in a bottom heat of 80° to 85°, the temperature of the house or pit ranging from 55° to 65°. The present condition of the samples does not enable us to determine their state when cut from the Vines.

Orchid and Gardenia Flower Buds Falling (S. M.).—Probably you have kept the Orchids named too dry at the roots, and though at this time of year liberal supplies of water are dangerous, yet the other extreme is fatal to the flowers. Give them as light a position as possible, and keep the peat and moss well moistened. This may save those that remain upon the plants. The flower sent in the letter is too much crushed to be recognised. The Gardenias are suffering in a similar way, either because they have had a check at some time, or because the bottom heat is insufficient. They should be plunged in bottom heat that can be kept at 80°, with an atmospheric temperature about 10° lower. If the plants are syringed twice daily the buds will develop quickly. If the pots are full of roots weak stimulants may be given, or, better still, a little artificial manure applied to the surface. In the later batches the roots must be kept steadily growing, or the flower buds when they appear will be puny if not deformed. In the majority of cases the deformity and falling of the flower buds of these plants is due to inactivity of their roots, and strong supplies of liquid manure during the time root action is defective. Strong insecticides will also cause the same results when applied as the buds are forming.

Profitable Flowers (W. F.).—There is a good demand for Bouvardias, but by far the best prices are obtained in provincial towns. The London markets would appear to be well supplied with them, large quantities being grown in Kent and Sussex especially, and as a consequence prices are low, from 3d. to 6d. per dozen sprays being all that can be obtained. Unless exceptionally well grown, whole houses being given up to them for a few weeks, they do not pay well at the London prices, but in the principal provincial towns it not unfrequently happens the prices range from 1s. to 2s. per dozen, and in this case Bouvardias are decidedly profitable. The doubles are the best for the purpose, as although the singles are the most beautiful they are not serviceable enough for the markets. The two favourites are A. Neuner (white) and President Garfield (pink), and a trial might well be given to Thomas Meehan (double scarlet) and Victor Lemoine (bright scarlet), this also being a double-flowering variety. For local purposes we can recommend Vreelandi (pure white), Candidissima (an improved Jasminoides), Dazzler (rich scarlet), and the newer President Cleveland (bright scarlet), these being very floriferous single varieties. If not unduly shaded by the Maréchal Niel Rose, an intermediate temperature being maintained, the Bouvardias would succeed far better than semi-double Zonal Pelargoniums, the latter, though flowering freely in heat, being most impatient of shade. For the markets you cannot have any better Pelargoniums than F. V. Raspail and La Cygne, the demand being greatest for these at Christmas, any scarlet and white flowers selling well at that time. Further hints upon Bouvardias, Zonal Pelargoniums, and other flowers for the markets will duly appear in our columns.

Cœlogyne cristata (Floral).—Your best plan is to allow the

material about the roots to become moderately dry, then turn the plant out of the pan and carefully work all the soil from amongst the roots. If you cannot do this with the fingers without the destruction of large quantities of roots, wash the soil from amongst the roots with tepid water; after this allow the plant to drain thoroughly, and then break it into pieces. If the pseudo-bulbs are crowded, we should trace out the rhizomes until the whole is broken up. On each rhizome there may be two or three leads. Some of these would be cut just in front of each lead, and all small pseudo-bulbs with a lead laid on one side. Even small ones that have no lead would be taken from those rhizomes that have large flowering pseudo-bulbs at the end. Those having three or four good leads need not be cut in all cases, they can be secured by means of a few pegs in the pot or pan. By breaking up the plant thoroughly, all old material is removed from amongst the roots. The pseudo-bulbs can then be sorted into three sizes, so that the largest, moderate sized, and small ones can be potted by themselves, while those that have to make back breaks should also be kept alone. Another plan is to work from amongst the roots a portion of the compost only, and then to cut the rhizomes and break the plant up into a certain number of portions, suitable in size to the pans or pots they are to occupy. This disturbs the plant less than the other method; but there are objections to it, which warrant us in advising you to follow the other system. The first is that a portion of decayed or decaying compost is left about the roots of the plants. Another objection is leaving the pseudo-bulbs in a more or less crowded condition and of various sizes. In potting the pots must be one-third filled with drainage, and over this a little moss or rough fibry peat can be placed, then fill the pot or pan with the compost in which the plants are to be potted, and which may consist of fibry peat and charcoal, or crocks, both may be used. Living sphagnum moss may be reserved for the surface. If you commence towards one side of the pot or pan you can gradually raise them to the centre, pressing the compost firmly about them. A few wire pegs may be necessary to secure them in their proper position. The rhizomes must not be buried below the surface. After the pseudo-bulbs have been placed evenly over the pots, you can make them firm by pressing portions of peat amongst them and at the sides of the pots. Your plant can be attended to at once, and should be placed afterwards in brisk moist heat. Dew the foliage with tepid water once or twice daily according to the weather until growth is commencing, when the peat may be surfaced with moss. At first, until they begin growing, water should be given carefully. Shade the plants from the sun after they have been broken up. Old pseudo-bulbs that have to make back breaks will have few roots of any value, and the rhizomes should be pegged on the surface of the peat.

Hardy Plants (Town Garden).—We know of no book of the nature which you suggest that would be likely to help materially, and we readily give the information you require. Snowdrops, Crocuses, Hyacinths, and Narcissus of various kinds would do in the position you describe, and should be planted in October. *Lilium candidum*, *tygrinum*, *californicum*, *testaceum*, and, if not too shaded, *auratum*. The latter can be planted now, the first and fourth in August after they have flowered, the others in October. The two first are the most useful and certain. *Myosotis* and *Daisies* would grow well amongst these for spring flowering. *Auriculas*, *Primroses*, and *Polyanthus* would also thrive in the shadiest place. These can be raised from seed sown in March and April, and grown outside anywhere in the shade until autumn, when they should be planted where they are to flower, or where they are to remain. The *Auriculas* are best taken up after flowering and replanted again where they are to flower towards the end of September or early in October; in the meantime they would do in any shady corner. German *Irises* of various kinds do splendidly in shady positions, and may be planted now or at almost any season of the year, but the best time is just before they start into growth. English and Spanish *Iris* also do well. They take up very little room, and some of the flowers are most beautiful. These are deciduous, and should be planted in autumn. The common white garden *Pink* will do well, and may be planted now. *Delphiniums* are good as tall plants, and can be raised from seed sown outside in April, or plants may be obtained and planted until the end of March. *Phloxes*, if not too shady, would flower profusely; plants of these should be obtained and planted during the next few weeks. *Anemone japonica* and its white form *alba* (Honorable Jobert) will succeed if the position is fairly open. These may be planted any time from October until April, the earlier the better if they are to flower the first season. *Geum coccineum* may be raised from seed, and strong plants put out during showery weather in spring soon commence flowering. In the lightest position *Asters novæ anglæ*, *novi belgi*, and several others would flourish, and should be planted in spring. *Campanula persicifolia*, with its variety *alba* and *flore pleno*, also *C. glomerata*, and its white form *alba*, as well as *C. Hosti*, if they are not too much shaded, will do well. These may be planted any time during the spring. *Dielytra spectabilis*, *Doronicum austriacum*, *Funkias* in variety, *Helenium pumilum*, *H. Hooperi*, and any of the varieties of *Hypericum*. *Lily of the Valley* can be planted after flowering, or any time from October to March. *Lychnis chalcidonica* and *alba* raised from seed sown at the end of March or the first week in April. *Oenothera Youngi* and *macrocarpa* raised from seed. *Rudbeckia Newmani*, *R. Drummondii*, and *Senecio*, *Doronicum* will also succeed. Where particulars are not given plants should be obtained and planted during the last week in March or early in the following month. The ground where they are to be planted should be deeply dug and liberally manured.

Peaches for Planting (S. T.).—You cannot do better than plant the Nectarine you name, Pine Apple. If you want a succession of Peaches, plant Grosse Mignonne, Bellegarde, and Barrington. If you plant Royal George it would ripen before you had finished gathering Grosse Mignonne. Alexandra Nohlesse is a splendid Peach, but tender in the skin, and is easily damaged; at the same time it is rather shy. Dymond is an excellent Peach, but not better than Royal George. If you could place the last-named in the coolest portion of the house, then we should prefer it to Bellegarde, for the flavour is superior.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (W. H. B.).—A solitary Apple may or may not be fairly typical of the variety, and your "last" specimen we are inclined to think is somewhat more conical than the majority. In all other characters it resembles the Norfolk Beefing, and that is possibly what it is. Reine Marie Henriette is a suitable companion Rose to Gloire de Dijon. (P. R. S.).—The Apple you send is, we think, Lord Derby, which sometimes keeps till this period of the year. When preparing the fifth edition of the *Fruit Manual* in 1883 Dr. Hogg says on page 135 that he then had fruits 4 inches in diameter and the same in height, and the description there given is applicable to your specimen. This Apple is not so well adapted for culture in the north as the south of England. (R. W. W.).—Your letter has been sent to us from the publisher's department, but we have not received an Apple which you say was "enclosed," nor can we find, on inquiry, any specimen in the department in question.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes, slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (A. F. S.).—1, *Asparagus tenuissimus*; 2, Insufficient without flowers; 3, *Siphocampylus hicolor*; 4, *Asplenium viviparum*. (W. G.).—1, *Nephrodium molle*; 2, *Onychium japonicum*; 3, Insufficient without flowers, probably an *Anthericum*; 4, *Asplenium viviparum*. (J. H.).—*Livistonina inermis*. (Australia).—1, *Drimys Winteri*; 2, *Raphiolepis ovata*.

COVENT GARDEN MARKET.—FEBRUARY 26TH.

Market very quiet, business consisting principally of foreign importations, such as Apples, Tomatoes and New Potatoes.

SOIL FERTILITY.

SOME recent correspondence which has appeared in the *Times* upon this subject has given rise to the question, "Is the earth gradually becoming less fertile?" or, as it has also been put, "Is there a loss of primal fertility in the soil?" By primal fertility we take it is meant the condition of virgin soil when first brought under cultivation, and chemists tell us that ordinary soil contains less than 4 per cent. of the essential elements of plant food, the greater part being derived from air and rain, to which must be added about 3 per cent. of fertilisers, consisting of clearly defined quantities of potash, nitrogen, lime, and phosphoric acid in order to insure a full crop.

Although the term of primal fertility is certainly vague and calculated to mislead, yet we are bound to welcome any discussion which tends to draw attention to the soil and its cultivation. But surely it must be apparent to everyone that there is some exhaustion of the soil by every crop taken from it, and that if we would do what is possible to insure a succession of full crops the soil must be kept stored with fertility by the systematic use of fertilisers. However different opinions may be as to the best form in which manure should be used, the fact remains that manure is indispensable, and it is equally beyond question that the best manure is that in which efficiency and economy are best combined.

It has been laid down by unquestionable authorities that the soil is superabundantly provided naturally with soda, silica, magnesia, sulphuric acid, chlorine, and ferric oxide. It derives carbon, oxygen, and hydrogen from the air and rain; it may also obtain some portion of the other manurial constituents from decaying vegetation. It may, of course, possess enough of lime naturally, as it undoubtedly does in certain formations; it may even contain enough potash; but the four chief fertilisers must be present in sufficient quantities for the requirements of each crop, and in our endeavour to store them in the soil it is to be feared some waste is unavoidable. That enough potash is present in the soil much more generally than was supposed has been proved by the widespread use of muriate of potash, to which Mr. Cook's remarkable success with the use of it in Barley culture at Flitcham Abbey gave rise. The fact that nobody else has obtained anything approaching the Flitcham results tends to show that it was decidedly an exceptional case.

Potash had a thorough trial last year in the experiments of the Bath and West of England Agricultural Society, carried out upon nine farms upon red sandstone, five upon chalk, and five upon other soil. The result of these trials in Barley culture affords additional proof of the value of nitrate of soda in combination with mineral superphosphates. The best dressing to Barley per acre consisted of $1\frac{1}{2}$ cwt. nitrate of soda, 2 cwt. mineral superphosphate, and 3 cwt. of common salt, and the value of this addition

of salt appears to be recognised by all those who were directly interested in the trials. Its low price and its beneficial effects should lead to a much freer use of it. On one farm a field which had been laid down for two years under seeds had no manure and yet gave better results than any of the other fields which had manure. The result is curious, but it is unimportant, as it is positively certain that the soil contained an ample store of plant food, and the test was, therefore, an unfair one.

If the superiority of the Barley in the unmanured field draws more particular attention to the nature and condition of the soil in fields selected for such experiments it will certainly do much good, for unless the drainage and porosity of such soil is equally sound the manure test cannot be a fair one. We but repeat an oft-told tale when we urge upon farmers the equal importance of drainage, mechanical division, and fertility. Without the two first the last is comparatively useless, and we could undertake with certainty that the crop of a well drained mixed soil field though unmanured should be altogether superior to that of heavy undrained land however highly manured. Light and heavy land may occasionally be found upon the same farm, but the difference in the nature of the soil might pass unnoticed by a visitor who was not prompted to look for it.

Primal fertility then is merely a comparative term, worthy of being classed with that of "season-proof land," which farmers in search of a farm have recently been advised to look for. Both terms are relative, and neither has a practical literal meaning; yet there is no doubt that under present conditions some land is not worth having rent free, while other land is so sound, is so readily stored with fertility, and the crops are so little affected by an adverse season that it is worth a comparatively high rent.

WORK ON THE HOME FARM.

Never was the value of thorough provision for the lambing more evident than it has been recently with a bitterly cold east wind often blowing hard. Exposure to it is most trying and exhaustive for young lambs, and both ewes and lambs have been kept in snug quarters in the lambing yards with plenty of clean straw for litter fresh daily and plenty of shedding for shelter. Especial care is taken to use only long clean straw, and to allow no chaff to be dropped about the yards, as it spoils the wool for sale later on. For cases of protracted labour ergot of rye has been used with tolerable success, but such success is not invariable, especially when the ewe carries a dead lamb. We have been able to withdraw such lambs from the womb, even when in a state of partial decay, by careful manipulation, but the shepherd requires two assistants to support the ewe during this trying operation, and he must be very gentle and patient. The withdrawal of the foetus is immediately followed by careful washing of the vagina with warm water, and one or two applications of warm carbolised oil with the syringe. If the ewe is otherwise healthy, and mortification has not set in, it may be saved by judicious feeding, and by another application or two of the oil. All such invalids are kept in a separate yard with a warm lodge in which the sheep can be shut in very cold or stormy weather.

Twins are not so abundant as they were last year, but the lambs generally are strong and healthy. Grass is plentiful, so are roots, and ewes with strong, forward lambs will now go to the Turnip folds whenever the weather is favourable. We prefer thatched hurdles for the north and east sides of the folds, and if the folds are large an inner line or two of thatched hurdles is always used for shelter by both ewes and lambs. There are plenty of sound green tops for the lambs, and some bran will be given them outside the folds as soon as they can eat it. Once get them well started upon the Turnips and bran, and growth quickens perceptibly. Good suckling, too, is of the utmost importance, and all care must be taken to sustain ewes well, and not suffer them to fall off in condition.

RATS AND OTHER VERMIN.

IF editors of periodicals and newspapers have really the intention of doing good, more than filling up the pages of their papers with quotations, they should give the article by your agricultural correspondent in last week's issue full publicity; it might perhaps have the effect of showing the true cause of the balance-sheet indicating a loss, by the inroads of vermin through carelessness and sheer laziness. If farmers were only partly as careful in preventing grain being destroyed as they are in protecting prize cattle, there would be no one more astonished than themselves at their good fortune, by simply taking thought and action to destroy vermin, and preserve the grain which they depend upon for a living. Exactly fifty years ago I lent a hand to the killing of 180 rats in a Wheat stack, and many escaped. The stack was completely tunnelled throughout, and not less than ten bolls of Wheat destroyed, which at

that time would be about £20 sterling. The rats that escaped fled to other premises, and destroyed many fowls and rabbits.

When rats take possession of buildings, allure them to one apartment having one entrance only fitted with a trap door. Feed the rats here on dainties, meat and drink, for the latter, if of the right sort, is enticing. After a few nights' regaling, draw the string, the trap goes down, and the rats are at your and dogs' mercy.—W. T.

OUR LETTER BOX.

Breaking up and Laying down Pasture (T. S. R.).—As you give no special reason for your alarm about wireworm in the soil of the old pasture ploughed a fortnight ago we may remind you that it by no means follows that because you have ploughed in turf you should have trouble from wireworm. If much wireworm has been seen during the ploughing it would answer best not to sow Oats this season, but rather to apply a dressing of 5 or 6 cwt. of salt per acre, and sow White Mustard 20 lbs. to the acre, to be folded with sheep as it comes into flower; then plough and leave it to nature till the following spring, and then lay it down to pasture with a crop of Oats. Good seeds may be had from any of the specialists advertising in our columns. If the old sods are not infested with wireworm then sow Oats as you propose, now drilling in with the seed corn 1 cwt. nitrate of soda, $\frac{1}{2}$ cwt. muriate of potash, $\frac{1}{2}$ cwt. mineral superphosphate, $\frac{1}{2}$ cwt. steamed bone flour to induce strong growth and a full crop, and sow the grass mixture for permanent pasture immediately after the corn is sown. The best horned cow after the Jersey is the Guernsey. In the opinion of many it is even better than the Jersey, for it is a larger animal and gives a proportionately larger quantity of very rich milk.

Manure Queries (T. M.).—"Nitrogen for Mangolds. Applied as a manure for Mangolds (with others) is sulphate of ammonia preferable to nitrate of soda or guano?" This question is timely and important, for the influence of nitrogenous manures upon Mangolds is remarkable, and it has been proved beyond question that nitrate of soda is the best form in which it can be applied to that crop. In the Rothamsted trials an average of 13 tons 17 cwt. of Mangolds for eight years was the result of a dressing of nitrate of soda alone, or 6 $\frac{1}{2}$ tons more roots than ammonia salts, and 2 $\frac{1}{2}$ tons more per acre than was obtained from the use of nitrogen in any other form. Pray understand that we do not recommend the use of nitrate of soda alone, but in combination with mineral manure and dung. We have frequently called attention to the value of dung for this crop, for its moisture as well as its fertility, and we always use it and sow on the ridge if possible. Perhaps the most satisfactory result of the eight years' average at Rothamsted was that of 23 $\frac{1}{2}$ tons of Mangold from a yearly dressing of 14 tons of dung, 3 $\frac{1}{2}$ cwt. superphosphate, and 550 lbs. nitrate of soda. We may remind you that the action of sulphate of ammonia is slower than the nitrate, yet it is quite possible that it might induce equal results if used in a moist climate or very wet summer. Sulphate of ammonia may be kept for a year without serious deterioration in a thoroughly dry store house with damp proof floor and walls. A moderate quantity of salt might be added with advantage to the manure mixture for grass, if used early before free growth begins. It is an admirable solvent, as well as a valuable fertiliser, and it will in future be used freely in all compound manures, for arable land especially. Basic slag would certainly be useful as a dressing for fruit trees, and it would answer for Strawberries if applied to a new bed, where its beneficial action would tell with the full development of the plants.

METEOROLOGICAL OBSERVATIONS.

REMARKS.

16th.—Fine, with frequent sunshine.
17th.—Cloudy morning; bright afternoon.
18th.—Fine and generally bright.
19th.—Bright and fine.
20th.—Dull early; damp and showery all day.
21st.—Dull and slightly foggy all day.
22nd.—Overcast throughout.

A dry but rather cloudy week; little range of temperature, and the mean remarkably near the average.—G. J. SIMONS.

TEMPERATURE AND VENTILATION.

—+—

AT all seasons of the year when plants or fruits are grown under glass it is absolutely essential to success that due attention be paid to the maintenance of suitable temperatures and atmospheric conditions for meeting the requirements of whatever may be under cultivation. During the summer, or ripening period, fluctuations in temperature are far less injurious than in spring, yet at no time can the work of regulating the heat and controlling the moisture in plant and fruit houses be ignored with impunity. It is true that as summer advances firmness of growth increases, and the firmer it is the safer it is against injury by the weather changes incident to the season; but even then errors or neglect lead to unfortunate results in the scorching of foliage, the premature decay of fruit, or the increase and establishment of a scourge of insects. All that will be granted by experienced men. A gardener must be on the alert at all times. He must be quick to perceive slight deviations from the routine of safety, and prompt to take action for the prevention of untoward occurrences that he may foresee to be imminent as the consequence of an accident or mistake. Necessary as is the habit of watchfulness on the part of the gardener, at no period of the year is it so essential as at the present time. Growth now in Vines and plants is forced growth, and in proportion to the forcing is the tenderness of that which is forced, and therefore its liability to injury by checks and chills that are bound to follow errors in judgment or inattentiveness in duty.

When a wave of winter invades the months of spring, as often has been the case, and doubtless will be again, then is the time for testing the value of the services of men who are entrusted with the charge of forcing operations in gardens. The earnest, anxious, watchful man is seldom taken by surprise. He appears to sniff danger in the air and prepares to meet it. It may come in the form of extreme weather changes more quickly than he expects, and with greater destructive power; but if expected and provided for, ill effects if not entirely frustrated will be considerably palliated. A period of abnormally mild weather is apt to throw men off their guard and engender a feeling of false security, and the longer the favourable conditions continue the greater the danger of a surprise that may end in disaster.

The weather for some days past has been of the most "trying" description for gardeners whose Vines, Cucumbers, Melons, and various tender plants under glass made good progress during the milder term preceding. The driving icy winds and storms of sleet have sought entrance through every chink and cranny, and lowered the temperature in many a structure to a dangerously low point for the tender occupants. This may not have been preventible in all cases, for in some structures imperfections are apparent, and in others the means of heating are obviously deficient to the practised eye. In such cases the gardener—who is a zealous man, and does all that is in his power with the aid of such coverings as he can devise, and sitting up half the night to save his crops and reputation—is profoundly to be pitied if he fails; and when such men who make those efforts do fail, as has more than once happened, they are the victims of circumstances, and it is neither right nor reasonable that they should suffer for failings not their own; but, on the other hand, when all that is needful is provided for the satisfactory conduct of operations under sudden and extreme weather vicissitudes it is strictly reasonable to expect that advan-

tage be taken of the provisions, and failure in this can only have one result—loss of reputation.

When Vines, for instance, are in full growth, either advancing to or passing through the flowering stage, a sudden and extreme fall in temperature may have unfortunate results, and especially if the temperature long remains so low that the leaves are seen to be suffering by a tendency to droop. This condition of the foliage demonstrates stagnation of the sap. It has for the time, in consequence of the cold, lost its fluidity, and cannot perform its health-giving mission. The check thus sustained by Vines at a critical time may not be recovered from throughout the season. When it arises through defects in the heating arrangements, and not inattention, it is clear the Vines were started into growth too soon. Many are the mistakes that have been made by attempting too early forcing in the absence of adequate means for carrying it to a successful issue, and it is far better under such circumstances to wait a few weeks and succeed at last, than to commence action too soon and fail.

Almost every spring a time comes when, under the best of attention, the requisite temperature in vineries and forcing houses can scarcely be maintained, and never without an extravagant, not to say outrageous, consumption of fuel. Yet the structures are supposed by the owners of them to be "well heated." They are under a mistake. When the fires in garden furnaces have to be kept in full blazing power as if for generating steam for propelling an ironclad or locomotive at full speed, that fact of itself is more powerful than all the arguments which can be advanced that either the boiler is too weak for its work, or the pipes are insufficient for the distribution of the heat required. Reducing the boiler power and piping in garden structures to the lowest possible limit, though a few pounds may be thereby saved at the outset, is a costly mistake, for apart from the liability of a breakdown, that is always a contingency not very remote under high pressure working, it increases the fuel bill enormously, and the imagined gain at the outset involves an immeasurably greater loss in the end. Moreover, the heat radiated from pipes in which the water is near the boiling point is, comparatively speaking, inimical to vegetation, for it deprives the atmosphere of moisture, and renders it specially suitable for insects.

While it is fair to recognise structural imperfections, defective arrangements, and initial obstacles to efficient working, the very important practical question arises—Is the best done that can be done with the means provided? It is clearly the duty of all men to act in accordance with the obligations thus involved, and there cannot be a doubt that gardeners, as a body, conscientiously and resolutely endeavour to make the best of the means placed at their disposal. If they did not they would not merit their positions. Most of them, however, are quite alive to the circumstances of the case, and know very well that the greater the difficulties they have to contend with, the greater is the credit in succeeding in spite of them. Hence the strenuous endeavours that men make under adverse conditions to show results equal to their fellow workers who are more favourably situated. It does not follow they succeed in this, but the effort to do so is in the highest degree commendable. It is very often a case of making bricks without straw, and it is questionable if any better adepts at this are to be found than within the gardening ranks. But all are not alike. Some are more lethargic than others, more prone to run risks, more self-indulgent, slower to discern the full force of small matters and what they regard as trivial mistakes; and it may safely be said that these are not men who are likely to attain to very high positions in their calling.

The provision and maintenance of suitable temperatures and atmospheric conditions in forcing houses at the present time are matters of the highest importance. It is impossible to devote too much thought to the work in question. It cannot be successfully conducted by clockwork or in a perfunctorily routine way.

Making up fires at a particular time regardless of their condition at that time, of the temperature of the structures, heat in the pipes, also of the present and prospective state of the weather, is wrong. All these things have to be considered, and are considered by men who acquit themselves the best in the work in hand. One person will wait an hour or more to have his fires in the best state for making up, while another fails to see the use of being so particular, and acts accordingly, trusting to chance that all will be right. In all cases of doubt as to the temperatures in the morning the man who intends to gain a reputation for trustfulness will prefer being out an hour or two too soon to half an hour too late. In the former case the man is master of the position, in the latter the position is master of the man.

It would be amusing if it were not painful to see the frantic efforts a man will make late in the morning to atone for his negligence on the preceding night. It is true he succeeds in raising the temperature and having the pipes hot by the time the sun is hot too. That is exactly what should be as far as possible avoided, for fuel then is worse than wasted, as the heat generated in the pipes is harmful rather than beneficial. Under the combined influence of fire and sun the temperature increases so rapidly that a choice of evils or dangers has soon to be made—namely, overheating on one hand, or excessive ventilation on the other. The less of this that is needed the better during winter weather in the forcing season. Widely opening the sashes for admitting a great inrush of cold, and consequently displacing an equal volume of warm moist air, is distinctly injurious to tender growth.

Much has been said for and against what are known as fixed temperatures at fixed times. As all experienced gardeners know, absolutely fixed temperatures—that is, no deviation from those prescribed—are not necessary for purposes of cultivation, and, moreover, cannot be insured; but for purposes of discipline rules are essential, and the more closely they are adhered to, subject to intelligent departures in accordance with verbal instructions, the more competent a workman becomes in the important duties with which he is entrusted in providing the conditions for healthy growth in fruit and plant houses during sharp frosty nights and bright sunny days in spring. No pretence is made of giving details for action, general principles only being considered, and these are conceived after several years of practice to be sound by—AN OLD HAND.

FLOWER CULTURE FOR PROFIT.

CHRYSANTHEMUMS.

(Continued from page 147.)

To succeed well with these the plants ought to be raised early and otherwise treated very much as are the plants that produce the prizewinning blooms. It is not yet too late to root a quantity of cuttings in boxes as being the least trouble, or pricked out in hand-lights or singly in small pots, gentle heat being desirable in order to expedite matters. Directly the plants are well rooted place them singly into 3-inch pots, keep them growing steadily on greenhouse shelves or other light positions, shift into 6-inch pots before they become badly root-bound, and harden off by the end of May. The final shift into 10 inch pots must not long be delayed, the plants being then set on a bed of ashes in double rows where they can be eventually supported by wires or longitudinal stakes in addition to a single upright stake placed early to each plant. From first to last no pinching back or stopping should be resorted to, the single stem as it lengthens and strengthens branching naturally. Select from six to a dozen of the side shoots, according to the vigour of the plants, remembering also the fewer shoots retained the finer the blooms eventually obtained, and loosely attach these to the stake. Some of the forwardest may, perhaps, show a bud in July or very early in August, but these may well be allowed to disappear again.

The crown buds showing from the middle of August onwards are what must be taken good care of, all the embryo side shoots but one surrounding these being carefully removed as early as possible. If this timely removal results in the swelling of the flower bud, also remove the other side shoot, otherwise the latter must be allowed to extend and form buds which this time will be easily preserved. Whether these late buds are surrounded by wood

buds or flower buds, all but the central one must be early picked out, and the plants being assisted with liquid manure will soon plump up those reserved. All must be housed before severe frosts are experienced. The plants may be arranged somewhat thickly in Peach house, vineries, or other high airy structures, a good circulation of air being maintained, in dull damp weather especially, with the aid of fire heat, the front and top ventilators being opened little or much, night and day, according to the external temperatures.

For about a fortnight before Christmas, and for any length of time subsequently, there is an exceptionally good demand for Chrysanthemums, red and white ones especially being largely used for church decoration. The specimen blooms realise relatively the best prices, though not more than 6s. per dozen are allowed, while the ordinary, or those obtained from non-disbudded plants, fetch from 1s. to 2s. per dozen wholesale in each case. There are now abundance of good late varieties, as far as light shades, but a good red variety would be a boon to market growers. J. Délaux, I believe, is fairly suitable, and this, however, not being strong grower, and only fit for producing large blooms, and Garnet. Other varieties suitable for producing late specimen blooms are Meg Merrilies, white; Ralph Brocklebank, yellow sport from the latter; Ethel, white; Yellow Ethel; Fanny Bouchardat, silvery white; Mrs. C. Carey, white; Carew Underwood, Baronne de Prailly, lilac; Belle Paule, white edged rose; Duchess of Albany, Grandiflorum, yellow; Moonlight, creamy white; Gloriosum, yellow; Prince of Teck, incurved white; Lord Eversley, incurved pure white; Hero of Stoke Newington, incurved purplish blush; Mrs. Norman Davis, incurved yellow; Fleur de Marie, white Anemone flowered, and Lady Margaret, white Anemone flowered. The only material difference in the treatment of these and the earlier flowering section, just previously alluded to, consists of taking the buds from a fortnight to three weeks later. Belle Paule, Meg Merrilies, Ralph Brocklebank, Ethel, Yellow Ethel, Mrs. Carew, Gloriosum, J. Délaux, and the "Teck family" are naturally late, and if the buds of these are taken about the first week in September, and the plants not forced in any way, they will rarely be past their best at Christmas. The other varieties, as well as many not mentioned, if prevented from swelling buds to the middle or third week in September, this being a comparatively easy matter, would also be at their best late in December. Some of our late taken buds of Belle Paule, Baronne de Prailly, and several other varieties were followed by nearly as fine as those which expanded early in November.

In addition to most of the previously mentioned late varieties, there are others particularly well adapted for growing in the ordinary manner. Fair Maid of Guernsey can be had very late, but on the whole the best late white for growing in quantity is the sturdy growing Boule de Neige, and a very fine companion will be found in Golden Gem, a rich bronzy yellow variety, and perhaps the most beautiful of all naturally late Chrysanthemums. These may be grown very much as advised in the case of the early varieties for bunching purposes, the latest stopping being made soon after all are turned out into the open. Golden Gem is also of sturdy growth, and if the plants are not stopped in any way, but are allowed to branch naturally, grand sprays of bloom can be had from them as late as the end of January, when these are worth not less than 6d. each, and are in great demand for ladies to wear. Late Chrysanthemums ought not to be overfed, strong liquid manure forcing them on rapidly, nor is it safe to retard in very cold or unheated houses. Give them a fair amount of fire heat, or sufficient to dispel damp, and abundance of light and fresh air. The tall plants that have produced a few rather early specimen blooms will, if kept in a moderately warm airy house, yield a number of serviceable side blooms down a considerable length of the stems, especially if not too closely disbudded, and very often many of the suckers thrown up from the roots will also form good flowers.

Any fairly good loamy compost will grow Chrysanthemums, but they well repay for liberal treatment in this respect. A mixture of two parts light loam to one of good leaf soil, with sharp sand added, is suitable for the cutting pots and boxes, and also, though in a somewhat rougher state, for the earlier shifts. For the flowering pots, the loam used ought to be of a fibrous and not too clayey character, and roughly broken up, the finer portions being discarded. To three parts of this add one part of leaf soil and partially decayed horse manure, and quarter-inch bones or bone-meal, at the rate of an 8-inch potful to every bushel of compost. The less fibrous the loam the more leaf soil should be added, and a very fibreless loam would be improved by the addition of coarser bones, charcoal, or crushed oyster shells. A good layer either of the latter or half-inch bones ought to cover the drainage crocks in the flowering pots, and the potting should be carefully and firmly

done. A little clear soot water administered occasionally after the soil is well occupied by roots usually sustains a healthy foliage, and a top-dressing of turfy loam and horse manure will do good in August. Good and careful watering, accompanied by frequent overhead syringings on hot days, and judicious applications of liquid manure after the buds are set, will do the rest.—M. H.

ON THE FLOWERING AND FLOWERS OF APPLES.

As the seasons come round we occasionally hear it said in early summer "There will be no Apples this year, the flowers having been destroyed by the spring frosts." In a paper which I read recently before the Society of Arts, London, on "Fruit Culture for Profit in the Open Air in England," I called attention to the fact that there were many days' difference in the date of unfolding of the blossoms of the different varieties, and that the general opinion was that the blossoms of the early blooming kinds were often destroyed when the late ones escaped. This is no doubt partially true, but not absolutely so, nor sufficient alone to account for a full or partial crop. There are other facts in connection therewith which I illustrated by the flowers of Peaches and Nectarines which were in bloom at the time the paper was read, and which is equally applicable to Apples. There is a difference in the size and substance of the petals which, to borrow a comparison from our own articles of dress, may be compared to that between a full and meagre, a thick and thin coat, and further in the form of the flowers, which if cupped or expanded may be compared to the difference between a buttoned and an open coat. So satisfied was I that these latter peculiarities influenced the crop of fruit that in the spring of last year (1889) I thought it worth while to note carefully the date of flowering, the size, shape and substance of the flowers and petals of some ninety-five varieties of Apples growing in precisely the same position and climate, and this table I now submit to the public.

DATE OF FLOWERING, NAME, SIZE AND SHAPE OF FLOWERS, SHAPE OF PETALS, SUBSTANCE OF PETALS OF NINETY-FIVE VARIETIES OF APPLES.

Column 1.—Size of flowers, S. small, M. medium, L. large.

Column 2.—Shape of flowers, Exp. expanded, Cup. cupped.

Column 3.—Shape of petals, N. narrow, M. medium, B. broad.

Column 4.—Substance of petals, M. medium, Thick, Thin.

The first column relating to the size of the flowers requires no further comment than that a large flower surrounding and in close proximity to the organs of fructification would have a greater protecting influence than a medium sized or small one. The second column relating to form is still more important from this point of view. It must, however, be remarked here that the flowers of some sorts are "cupped" from the time they open till they fall, whereas others are "cupped" when opening, gradually passing into the "expanded" form, and others, again, are expanded from the beginning till they fall.

The third column relates to the size of the petals which compose the flower, some being narrow, leaving openings between them, others closing completely, and some even overlapping. In the latter cases there is, I apprehend, a much larger amount of protection afforded to the delicate embryo. The fourth column relating to the substance of the petals cost me the most thought and time. The difference here is in some cases so slight as to require a very sensitive touch to realise, although I believe it is not without influence on the crop.

Many inferences may be drawn from the facts recorded in the above table. I will only instance one. The popular opinion that early flowering sorts should be avoided would seem not absolutely correct. Two of the earliest flowering sorts, "Irish Peach" and "Duchess of Oldenburg" are constant bearers, which is due probably to the protection the embryo receives from their large cup-shaped flowers; whereas two of the latest flowering sorts, "Bess Pool" and "Northern Spy" are shy bearers, which may be due to their natural constitution, but is open to the suspicion of being influenced by the later frosts on the organs of reproduction which are less efficiently protected. But here, as in all

cases of this nature, exceptions will occur.—WILLIAM PAUL, *Paul's Nurseries, Waltham Cross, Herts.*

SPINACH.

WHERE Spinach is wanted all the year round it requires some attention to have an unbroken supply. The two periods which are the most likely to see a scarcity being during winter or early spring, and in early autumn or late summer. The winter and spring season can only be bridged over by means of one or two large sowings, and the warm season by small sowings made at short intervals. I do not know whether the having a somewhat light soil to deal with has anything to do with it, but the fact remains that this is one of the most troublesome of all vegetables, and my experience shows that it is necessary to divide its cultivation into two fairly well defined sections, the first for the summer and autumn supply, and the second for winter and spring.

The earliest sowings present no difficulty. A few dozen yards in lines made every ten days, beginning with the first suitable weather in February, secures an ample supply to come in the beginning of May and before the autumn sown crop is fairly over. About the end of May the fresh sowings need special attention, and right on through the summer months extra care is needed. If there is time for the work shallow trenches should be made wide enough to get two rows in at 10 inches apart. In the bottom of the trench a thickness of 4 inches of decaying manure should be placed, 3 inches of soil above that, then the seed, and another 3 inches of soil, leaving a hollow of about a couple of inches below the general level. If weather be dry the bottom of the trench should be watered before placing in the manure, and the soil on which the seed rests must be moistened before sowing, though it is not necessary to moisten the top layer. The seed very soon germinates, and if the plants are 4 to 6 inches apart that will be quite close enough. Whenever drooping is noticed water must be run down the middle of the trench; it need not be much, only sufficient to moisten the manure. This treatment gives medium-sized leaves and staves off flowering.

The winter supply is sown on soil which has been cropped with second early Potatoes, and the seed is sown from the beginning of August until the beginning of September. In some seasons the earlier sowings do better than the latest, in others it is just the reverse; but all sowings made during the period between these dates do well. No dung is given to the crop, as richness of soil at this season is not wanted, but rather a short firm growth. The young plants should be thinned from 6 to 9 inches apart, and the rows must be at least 12 inches the one from the other. Instead of rows a few dozen yards long in the aggregate the winter crop must be of some magnitude. Where constant pickings, say from three to five a week, are made all through the winter it requires a good quantity of plants to bridge over the season of non-production of foliage, 25 to 30 square poles not being too much. In picking only a few leaves should be taken off a plant at one time, and these well developed. When growth sets in on the return of spring a slight dressing of nitre will be found of great benefit in quickening growth. The crop can, of course, be partially destroyed when leaf production sets in vigorously, and the entire crop should be off the ground before the flowering stems make progress, as at this stage Spinach becomes an exhausting crop. As to the best variety to grow, and where one has to give "substitutes" the go-by, there is something in a variety slow to rush into flower. The most promising I have tried, and I have tried every variety I have seen offered, is one named "Paresseux de Catillon." This, the common round-leaved for spring and winter, the prickly seeded for the latter season, and the monstrous Viroflay, are the varieties I am growing this year.—B.

TREATMENT OF MANURES.

MR. BISHOP's treatment of artificial manures is rancorous; he never omits an opportunity of abusing them, and never assigns any substantial reason for so doing. He says that while with most artificial manures some fail, home manure is sure to suit the soil in its district (implying, I suppose, that out of its district it might not be so suitable). He appears to have been much struck at seeing an artificial manure manufacturer dressing his land with farmyard manure. I should have been equally struck if the manufacturer had not utilised his home manure. No one disputes the value of farmyard manure, but that is no reason for abusing another manure as good or better. Mr. Bishop goes on to say that in his opinion more disease has been created amongst vegetation by artificial manures than we are aware of, but gives no justification or explanation of this mysterious charge. In the opinion of many

gardeners, and others equally well informed, insects are created by those dull, heavy days when they knowingly inform us there is a blight in the air, and subsequently with great satisfaction to themselves prove their statements by showing the presence of the insects on the various plants. To me it appears that the two opinions are of equal value.

All manures sold as artificial are not suitably compounded for the several crops for which they are intended; some are not genuine and others are used unskillfully. In such cases failures may be expected.

Much ignorance prevails both as to the nature and the proper application of artificial manure. There are some who are so ignorant as to suppose that because a very small quantity of manure produces a beneficial effect therefore a much larger quantity will give a much better result. Others imagine that because such manures as superphosphate of lime, sulphate of ammonia, or nitrate of soda are under certain circumstances most powerful fertilisers they are equally so under all. A plant is a complex structure of many materials, all of which are indispensable and very rarely interchangeable (in certain plants, principally those which grow in proximity to the sea potash takes the place of soda when they are cultivated inland). The principal materials which specially require the attention of the cultivator are phosphorus, potash, and lime, together with nitrogen. The other materials not less indispensable are usually present in sufficient quantities in ordinary soil.

The most fertile soil contains but a limited quantity of these materials, and each successive crop reduces that quantity until the time arrives when sufficient of one or more of them is no longer present, then manure becomes necessary; but it is useless to supply superphosphate if there be not sufficient potash, or nitrogen if one or more of the other materials be absent, consequently many have failed with artificial manures through omitting to supply the deficiencies of the materials necessary to perfect the structure of the plant. If only one constituent of a plant be absent from the soil, though a full supply of all the others be present, the plant will not thrive or even grow. This explains many failures attributed to artificial manure, which are in reality not due to the manure, but to the ignorance of those who apply it.—EDMUND TONKS.

NOTES ON EARLY ENGLISH HORTICULTURE.

(Continued from page 41.)

LONDON and Wise, chief gardeners during what might be called the Dutch era in our country, left their impress on many establishments besides their own, for their services were much sought after by the patrons of horticulture, yet their style was only temporary. Addison, greatly charmed by some changes Wise had made in the old part of Kensington Gardens, where he transformed a series of gravel pits into winding and terrace walks, compared him to an epic poet. Certainly his poetry did not long continue in fashion, the formality of the arrangement of gardens under this régime had a quaintness and oddity about it, but it was too artificial to be pleasing. Perhaps, Blenheim Gardens, as they, till about sixty years ago, presented one of the best examples of planning done by this firm. The principal flower garden was a copy of one at Versailles; a lake or large pond occupied the centre, and it was surrounded by circular paths, with shorter ones connecting these. Wanstead House, Essex, once notable as the residence of Wellesley Long Pole, was another place laid out by London and Wise, and its park was considered a fair sample of their arrangement of avenues and shrubberies.

Hampton Court grounds were placed by William III. in the hands of these gardeners for re-arrangement; they are supposed to have planted its labyrinth or maze, though some think this of older date, and formed terraces in the privy or private garden, cutting and disfiguring also many of the evergreens which had been introduced by Stuart gardeners. They constructed pits in the kitchen garden for the production of early vegetables by earth heat, then a common practice. One device of the gardening of that age was certainly a good one; this was the placing here and there what were known as "prospect towers," not usually carried to any great height, but structures with seats, so far elevated that a garden or path could be viewed in a different aspect from what they present at the ordinary level of the eye. It was when the taste for the Dutch style was fast dying out that Dr. Blackwell, possibly a pupil of Wise's, an Aberdeen man, of somewhat versatile genius, engaged to lay out the grounds of Canons, near Edgware, where the wealthy Duke of Chandos built a mansion in 1712 (though some have conjectured that the work was chiefly done by the architect James, of Greenwich, who may have studied horticulture, as he translated Le Blond's book on agriculture).

However that may be, Dr. Blackwell was in the Duke's employ; he was acquainted evidently with botany and ornamental gardening, closing his life very singularly in Sweden, where he was executed for a supposed plot against the Government. His widow did some service to horticulture, as we shall see hereafter. The gardens of Canons speedily became the talk of the country all the more because they were satirised by Pope.

"His gardens next your admiration call,
On every side you look, behold the wall!
No pleasing intricacies intervene,
No artful wildness to perplex the scene;
Grove nods at grove, each alley has a brother,
And half the platform just reflects the other;
The suffering eye inverted Nature sees,
Trees cut to statues, statues thick as trees."

It may appear odd to attribute any influence upon British horticulture to such men as the poet Pope, and Addison, distinguished in prose, but both did service by showing what were the principles which good taste invites us to follow. Addison threw out hints in several of his essays, and Pope's paper on "Verdant Sculpture" in the *Guardian* led men to see how foolish it was to study how trees and plants might be treated unnaturally, whether singly or in groups. Nor were they simply theorists, each tried practical experiments upon a small scale; Pope at Twickenham, where he managed to do a great deal within the limited space of two acres. Addison had a retreat at Bilston, near Rugby, Warwickshire, and his walks and gardens remained many years intact after Pope's were swept away. Two things they specially opposed—the introduction of many needless walls, because shrubs could be so arranged as to shield each other from cold winds, and also that wholesale lopping which weakened many species, besides disfiguring them. Stephen Switzer, who had worked for a time under London and Wise, and followed their methods, seems to have been one of the first to adopt those improvements which led on to the modern style of gardening. Our forefathers had the odd idea that we were indebted to the Chinese for the change, but in fact the so called Chinese style was in some respects quite as stiff as the Dutch. Switzer had a garden at Millbank, near Westminster, and apparently a shop opposite the Court of Common Pleas, with a sign of "The Flower Pot," and was one of the early seedsmen. Amongst other things he found time to publish a work in three volumes entitled "Ichnographia," illustrated by copperplates, containing particulars of the various ways in which the grounds of a residence might be laid out, with a few remarks on agriculture. This came out during 1718, and in 1724 he wrote "The Practical Fruit Gardener," which was followed in 1729 by another work upon the rapid raising of kitchen vegetables.

About the beginning of that century the increasing demand for vegetables in and near London had led gardeners to study methods for hastening crops and obtaining a quick succession. For centuries the bulk of vegetables required in the metropolis was produced on the north and east sides, especially on the former, where, along the City Road for instance, many of the citizens had gardens in which they raised, some of them, more than they needed for their families, and allowed their gardeners to sell the remainder. By-and-by the advantages of the west of London were seen, and particularly its suitable soil and milder temperature. Thus in the district of the neat houses during the reign of William III. (what is now South Belgravia) about 150 acres of land, lying rather low, was kept well fertilised by stable dung chiefly put on, it is said, at the average of sixty cartloads to the acre. It was the first place where Liguorice was grown in any quantity, and much Asparagus was raised here, the King's pronounced liking for this esculent having brought it into public favour. Evelyn, however, thought the large Dutch kind was not nearly so agreeable as the English kind previously cultivated. He notes the fact as curious that heads were grown weighing from 4 to 7 ounces each. A special variety of Broad Bean became very celebrated, this having been first sown at Windsor by a gardener who received the seeds from Holland. There was an influx of French gardeners also about this time, and one of these introduced the Fulham Pea, long cultivated in the gardens of that suburb; to the French also in that district is attributed the extensive cultivation of herbs used for flavouring.

The historic nursery of Fulham, started by Gray in or about 1700, marked another era in the progress of horticulture. A large number of plants were received here from travellers in both hemispheres, and the firm purchased from the Bishop of London a collection of rare species obtained by Bishop Compton. Though a doubt has been thrown upon the point the evidence tends to show that the first *Magnolia grandiflora* was planted at Fulham, it lived till thirty years ago. The firm had early specimens of the *Ailantus*, the American Nettle Tree, of *Sophora pendula*, *Wistaria*

sinensis, and other species now growing throughout the country. An evergreen variety of the Oak was raised at Fulham, presumably from seed.—J. R. S. C.

LINUM ARBOREUM.

FOR cool houses, such as that in the Royal Gardens, Kew, or in fact any structure where frost can be excluded, this *Linum* is well adapted, and its bright yellow flowers are produced over such a long period of time that the utility of the plant is materially increased. Several *Linums* and their near relatives are already favourites in greenhouses, but *L. arboreum* is not so well known as *L. trigynum*, and its flowers being smaller it would not attract so much attention at first until its merits were recognised. It becomes quite shrubby in habit, attaining a height of several feet, and flowers freely from the apex of the branches.

FIG. 27.—LINUM ARBOREUM.

It is an old inhabitant of botanic gardens, and was introduced from the Levant in 1788 by Dr. John Sibthorp.

Ordinary light loam with a moderate proportion of sand suits this *Linum*; but good drainage is required, and if the soil be somewhat heavy a proportion of leaf soil will be found beneficial. It can be increased by cuttings, but these require care, as they do not produce roots very readily. Seeds are not freely perfected, and for a number of years no seed was obtained from plants in this country. It is not included in the Kew list of seeds available for distribution.

YOUNG TREES IN FROSTY WEATHER.—It not unfrequently happens that fruit trees arrive at their destination just when a severe frost prevails. It is very certain no practical man would think of permanently planting these newly received trees either while the frost is in the ground or when it has only just left it, the state of the ground in both instances being altogether unfavourable for this important work. Should the frost be only just commencing, or only moderately severe, the trees may safely be unpacked, and all be thinly and carefully laid in by the roots in some convenient spot for the time being. For several reasons it is most unwise to lay them in much as received

or in great bundles, but all the roots should have their broken ends cleanly cut off, those much damaged being cut out, and be then evenly surrounded with fine moist soil. A liberal covering of strawy litter over the roots and a little over the tops as well will tend to protect from severe frosts and drying winds. Thus treated the roots keep plump and fresh, and if unavoidably kept laid in for several weeks the wounds will also be healed somewhat. To leave the trees in the bales just as received in a dry shed for several days is a very great mistake, as the chances are the greater portion of the roots will become most injuriously dry, and a severe check to the trees be the sure consequence. If the bales cannot be unpacked owing to the severity of the frosts, then ought they to be placed in a moist shed or cellar where no frosts or drying winds reach them, must be unpacked at the first favourable opportunity, and if any of the roots are found to be very dry immerse them in water for five or six hours.—W. I.

FREESIAS.

THESE bulbous plants have several qualifications befitting them for a more prominent and general notice, which may be found in their pure colour, delightful scent, ease of culture, and free blooming properties. It is a matter of surprise that they are not more generally grown, especially seeing that scented flowers are so much sought after, and those unpossessed of perfume, by many persons, lose favour more or less accordingly. That they are easily cultivated certainly cannot be disputed, for they require really a shorter season of growth than even the *Primula* or *Cineraria*; the generous provision commonly accorded either of these plants during the actual growing term would command profitable returns for the labour expended, and, moreover, their blooming season is a period when white flowers are greatly in demand.

One error in their culture with many growers is in according them too much coddling or warm temperatures, causing an undue extension of growth, and consequently a weak flower spike. I have hitherto made the same mistake, but a vigorous specimen presented me by an esteemed friend and good grower has prompted a desire to adopt a more rational course in future. Naturally so good an example of culture induces anyone interested to inquire the course pursued, whereby the same results may be achieved, and I was fortunate in having a friend ready at all times to give advice, which has always been found reliable to act upon. His bulbs are selected in sizes for potting in August, placing about six of the largest bulbs in a 5-inch pot; the smaller ones are, when necessary to extend the stock, grown more thickly in the same or larger sized pots for blooming in subsequent years. The soil used for potting is a simple though substantial mixture. Good turfy loam dug from a deer park—what an enviable source of supply!—forms one-half of the bulk, the remainder being made up of leaf mould, pounded charcoal, and sand. The bulbs are covered, though not deeply buried in the soil, and firm potting induces a sturdy growth. They are at once placed in a cold frame together with *Lachenalias* and *Cyclamen*, and watered according as the condition of the growth directs. Here they remain as long as the state of the weather allows, or rather until frost makes their well-being uncertain. A shelf in a cool greenhouse is where they pass the early months of the winter, from which they are selected in small supplies of from one to two dozen, choosing of course those most advanced towards blooming, for placing into slightly warmer quarters to excite them into earlier bloom. Strong heat is highly detrimental to them, and should be strictly avoided, and they need at all times a light position for ensuring robustness. As the pots become full of roots liquid manure may be given at every alternate watering, which acts favourably in strengthening the flower spikes. Individual flowers do not last long in perfection, but happily a whole spike is not perfected spontaneously, the decaying flowers being followed by fresh expanded ones in quick succession, thus forming a long continuance of their desirable fragrance. For bouquets, wreaths, sprays, or any kind of decorative purpose they constitute a very conspicuous object, and anyone having such to cater for would probably find an outlay on *Freesias* a profitable investment.

Some idea may be formed of their floriferous disposition under good and liberal treatment, when it is stated that as many as eighty blooms have been counted on six plants grown in a 5-inch pot, and although this may not represent the average number they do not fall very short of it under the system pursued by the grower previously referred to. Attention to the plants must not be relaxed directly the flowering is over, as in a great measure on this depends the issue of ultimate success or the contrary. Continue watering them so long as growth is apparent, and when this stage is completed allow them to dry gradually, and assume their term of rest without further interference. They may either be stood on shelves in a cool house or in a cool pit after flowering, but wherever it may be let them be so placed as to get the full influence of

sunshine for inducing full maturity, and success must inevitably follow.—W. S.

NOTES ON FRUIT TREES—APPLES.

SINCE 1845 (when I was a stripling of ten and began to read such gardening literature as came within reach) I do not think so much has been written on fruit cultivation during the first four decades as during the last five years. Now everybody seems to have Apples on the brain. In 1848 Dr. Hogg, in the first edition of his "Fruit Manual," drew attention to the benefit to be derived by growers of fruit from a knowledge and adaptation of the choicer and most useful varieties. Since then other editions have appeared, demonstrating that by a judicious selection as fine, if not finer, fruit could be grown in our gardens and orchards as in any part of the world. Every requirement—the connoisseur who sought for quality, and general consumers who value fruit not so much as a luxury but as a necessity of life—are duly catered for, viz., a knowledge of the "characteristics and merits of fruits and fruit trees as they are produced when cultivated among ourselves at home," is given in the later editions, so that our impotence in preventing a foreign fruit invasion is wholly without excuse. Apathy and indifference to the fact that we were importing Apples which might be prevented by utilisation of the resources these isles possessed became awakened by the poor returns to the grower of home produce. The unattractive sour-looking, crab-like produce of the home orchards were driven out of the markets by the cheery, bright, clear skins, good using properties, through size or evenness of sample of the produce from Nova Scotia. Mayors of towns and cities, aided by councillors in public meeting assembled, claimed that the soil and climate of the United Kingdom would grow as fine fruit as that barrelled and exported from America, and all needed was to have attention arrested and interest awakened to the benefits of fruit culture to lift the farmer and small holder of land out of the "slough of despond" in which they had been so long floundering. But it was seen by those who had made a life study of fruits and fruit culture that nine-tenths of what was uttered at meetings or published in the newspapers partook more of the ideas of the enthusiast than of the experienced pomologist. Matter so lavishly distributed was promptly discounted by the "horticultural press." It was pointed out that though fruit can be grown in this country equal to any imported, success only attended intelligent culture, and that, though fruit could be grown at a profit, there was nothing like the money to be made, even in the most favoured circumstances, that enthusiasts imagined. Experts may gain experience by speculation without incurring loss, but the rank and file will be best served by a safe and common sense investment.

In looking at the produce of orchards from a consumer's point of view how many of the varieties grown are comparable to American Apples for any characteristic the consumer appreciates? Large handsome fruits, good alike for cooking or dessert? Having taken note of the varieties that nearest approach the standard in those respects, and comparing the fruit with American, I am urged to the conclusion that, strong as we undoubtedly are in autumn and early to midwinter fruit, we fail lamentably in late winter and spring varieties, when the finer and better kept American Apples tell so disastrously against British produce. Anyone with a garden can have Apples from September to January inclusive, but it is later, from mid-January to May, that large, handsome, well kept fruits of table and culinary utility pay best. That we practically have any at that time comparable to Baldwin, Newtown Pippin, or Northern Spy requires much assurance to affirm. True, we have a number of high-coloured and high-flavoured varieties, which, acceptable and appreciated as they may be to cultured taste, have too much skin and core—too much waste in comparison with the flesh to merit acceptance by the general public—the great factor to be reckoned with in the production of Apples for profit. Let us now proceed to a diagnosis of

VARIETIES SUITABLE FOR TABLE OR COOKING.

Early.—Lady Sudeley; large, pale yellow, streaked red or crimson, handsome. August and September. A comparatively new Apple of great excellence, either for small or large culture. Worcester Pearmain; medium, yellow almost completely covered with bright red, less so on the shaded side, handsome, free bearer. September and October. Wormsley Pippin; large, rich golden, orange on the sun side, clear yellow on other parts, free bearer. September and October.

Midseason.—Cox's Pomona; large and medium, yellow, much streaked with bright crimson, beautiful, flesh tender, moderate bearer. October and November. Harvey Apple or Dr. Harvey; large, pale yellow, flesh tender, free bearer. October to December.

Blenheim Pippin; large, yellow, tinged red next sun, handsome, flesh tender, shy bearer on young trees. November and December. Baxter's Pearmain; large, pale green, tinged red, deeper on sun side, flesh firm, free bearer, even in adverse seasons. November to January. Cobham or Golden Ducat; large, clear yellow, a little streaked with red on sun side, not unlike Blenheim Pippin, flesh tender, early, and abundant bearer. November to January. Gravenstein; large or medium, waxen yellow, streaked crimson, handsome, flesh rather firm, moderate cropper. October to December. Lady Henniker; large, yellow flushed crimson, and streaked, handsome, flesh tender, free bearer. Lewis's Incomparable; large, red streaked crimson on sun side, yellow on shaded side, faintly streaked red, strewed with russet dots, very handsome, flesh firm. December to February. King of Tomkin's County; large, greenish yellow, streaked red, very handsome, flesh tender, free bearer. December to March. An American Apple, which in this country does not ripen, or rather hangs late on the trees, and keeps remarkably well until April or May. It may not suit all soils and situations; when grown against a wall with southern aspect magnificent. Royal Pearmain or Herefordshire Pearmain; large or medium, greenish yellow, red on sun side, with deep coloured streaks, becoming bright crimson when maturing, flesh rather firm, free bearer. November and December. Harvey's Wiltshire Defiance; large, sulphur yellow, deeper on sun side, very handsome, flesh rather firm, good bearer. October to December. Lemon Pippin; medium, yellow, flesh firm, good bearer. November to January. Reinette de Canada; large, greenish yellow, brown on sun side, flaked russet, flesh rather firm, good bearer. In good soils and warm situations this is a remarkably fine Apple. November to January. Washington; large, yellow, streaked red, very handsome, flesh tender. October to December. Although this is an American Apple it promises to be a good grower and cropper, especially so in good situations.

Late.—Dutch Mignonne; medium, greenish yellow covered with streaks of red and crimson, flesh firm, great bearer. December to April. Bess Pool; medium, yellow, washed and striped red on sun side, faintly streaked on shaded side, handsome, flesh firm, does not bear well on young trees, an uncertain bearer. November to March. Barnack Beauty; medium, greenish yellow, streaked red, handsome, flesh firm, free bearer. February to April. Balchin's Pearmain; medium, lemon, crimson on sun side, flesh firm. March to May. London Pippin; medium, pale yellow, brown or red on sun side, flesh firm, free bearer. November to April. Calville Malingre; large, slightly yellow on shaded side, deep red on side next sun, red streaked, very handsome and distinct, free bearer. January to April. I have not seen this otherwise than in a warm situation—i.e., well sheltered and well drained soil, but it seems to have a good constitution. Northern Spy; large or medium, greenish yellow changing to rich yellow, crimson on sun side, streaked dark crimson, becoming brilliant as the fruit matures, very handsome, flesh tender, pleasingly aromatic. Does not bear well when young, evidently growing too freely, and is apt to become very much crowded in growth, therefore requires to have attention in keeping the heads open. Though an American Apple it thrives well in sheltered situations and properly drained soil. The fruit sent from the Canadas or northern seaboard States is usually conical-ovate in form, but in this country the fruit is less so, yet in no sense round, but ovate, less inclined to be conical than American grown fruit, and the flesh in English grown fruit is firmer. To my taste this is the finest of all Apples. December to April. Like Worcester Pearmain and Peasgood's Nonesuch, Northern Spy is covered with bloom like a Grape.

On the hypothesis that an Apple for market purposes should be large in size, high in colour, or otherwise taking in appearance, with a tender flesh (or if firm falling when cooked), so as to make it acceptable in a raw state, and of greatest usefulness for general consumption, that is the Apple for the million. If an Apple be sweet enough to render it palatable for eating it surpasses as a culinary one those that require a deep dig into the sugar basin. An Apple, therefore, that is good as a table and cooking variety is most economical, and it becomes a question whether the buyer shall invest in sour fruits and purchase sugar to make them palatable, or purchase fruits that are so rich in saccharine matter as to render it acceptable to all palates in a raw state, and requires little if any addition of sugar in a cooked state. We have, of course, to decide between importing Apples or importing sugar. Another feature of the Apples that are good for cooking and dessert is that they have generally a tender flesh, being at the most crisp, particularly as regards the American varieties—viz., Baldwin, Newtown Pippin, Northern Spy, and Golden Russet, which are the varieties I have seen most of and used to maintain a daily supply of fruit from November to May, and as such are suited to delicate stomachs. It is all very well to laud a Ribston Pippin or some other hard firm fleshed variety to the skies on account of their surpassing excellence

of flavour, but it is another thing when the eater is a victim to dyspepsia, who eating a hard Apple may suffer agonies. In more ways than one the grower has not been in "touch" with the consumer, therefore I will proceed to a further digest of the varieties of Apples for the special purpose of dessert and cooking respectively.—G. ABBEY.

(To be continued.)

EVENTS OF THE WEEK.—The horticultural meetings for the week are as follows:—British Fruit Growers' Association to-day (Thursday), at 5 P.M., in the Horticultural Club Room, Hotel Windsor; the Royal Horticultural Society's Fruit, Floral, and Orchid Committees meet at the Drill Hall, James Street, Westminster, at 12 noon on Tuesday, March 11th; the usual monthly meeting of the members of the Horticultural Club will also take place on Tuesday at 6 P.M., the subject for discussion being Plant Hybridism; the first spring Show of the season will be held at the Royal Aquarium, Westminster, on Wednesday, March 12th. Other Society meetings are the Royal Society, at 4.30 P.M., Thursday, March 6th; and the Linnean Society, at 8 P.M. on the same day. The Royal Botanic Society, at 3.45 P.M., on Saturday, March 8th; and the Society of Arts, at 8 P.M., on Wednesday, March 12th.

— **THE WEATHER IN THE METROPOLITAN DISTRICT** during the past week has been extremely wintery and of a more severe character than previously experienced throughout the season. On Saturday snow fell nearly all day, with the result that by night it was 4 to 6 inches deep. This was followed by frost and more snow on Sunday and Monday, with a keen north-easterly wind. Very low temperatures have been registered in some situations. On Monday the thermometer was down to 16° and Tuesday to 14°, while we have heard from one reliable observer, who states that his thermometer was down to 10° on Tuesday morning. In town a heavy yellow fog prevailed until midday, but in the suburbs the day was extremely bright and sunny. At Greenwich the minimum registered was 13°, or 23° below the average, and 4° lower than any March temperature recorded there since 1845. Similar observations were taken in other towns, the record at Dungeness being exactly the same as at Greenwich. Towards evening on the 4th the wind changed to a south-westerly direction, and there was a rapid rise in temperature. At 8 P.M. on Wednesday the temperature was 40°, or 26° above that observed at the same time on the preceding morning. Writing from Cardiff on the 3rd inst. Mr. Pettigrew says:—"We are having sharp frost; the thermometer registered 10° of frost this morning. It is dry and bitterly cold. It will do good in keeping the fruit buds back."

— **THE WEATHER IN THE NORTH.**—The days generally during the past week (24th February to 3rd March) have been clear and cold. The nights, with one exception, have been frosty, 8° being registered on two nights, and 13° (the lowest of the season) last night. A good deal of bitter east wind has prevailed. The barometer continues very high. The sowing of Beans is being carried on under conditions highly favourable for our heavy coarse land.—B. D., *S. Perthshire*.

— WE see it announced, but we have no official authority for stating it, that MR. JOHN WEATHERS of St. Albans has been appointed Assistant-Secretary of the Royal Horticultural Society.

— **"TULIPIANA."**—I should like much to know if the work "Tulipiana" was finished beyond the four coloured plates in the fraction of the work bound up in Sweet's volume. They are works of art, beautiful in their colouring and execution.—D.

— **MANY** will learn with much regret that MR. MAURICE YOUNG of Godalming died on the 24th ult., at the age of fifty-six years. He followed his father as nurseryman in the town named above, and carried on the business for a number of years. Mr. Young possessed a good knowledge of landscape gardening, and was respected by a large circle of friends. His death resulted from inflammation of the lungs following an attack of influenza.

— WE are informed by M. Lucien Linden that the meetings of L'ORCHIDÉENNE at Brussels will in future be held on the second Sunday and Monday of the month. They will be open to visitors on Sunday from half-past one to six o'clock, and on Monday from 9 A.M. to 12 P.M., and from half-past one to six o'clock. The morning meeting of Monday is specially reserved for members of L'Orchidéenne.

— **BLLENHEIM PIPPIN APPLE FOR PROFIT.**—Mr. S. T. Wright, who is a stranger to the writer of the article to which he refers, and an extensive and successful cultivator of fruit, remarks—"I fully agree with the leader on page 145. I cannot understand any practical man recommending the planting of this Apple for profit. If I were asked to name varieties not to plant I should head the list with the Blenheim and place Peasgood's Nonesuch second."

— **PYRUS JAPONICA VIRGINALIS.**—I cannot too highly recommend the foregoing for flowering in a cold house at Christmas and onwards. I have a bush plant growing in a pot that is flowering with wonderful freedom for its size. It came into flower about Christmas, and it appears likely to remain in bloom for the next two months, as it appears to put forth fresh buds almost daily. The flowers are large and pure in colour. They are slow in expanding at this season of the year, and when developed last for a long time. I can heartily recommend it.—R. D.

— **GARDENING APPOINTMENTS.**—Mr. E. Binfield, who has been foreman at the Froyle Park Gardens for the past three years, has been appointed head gardener to J. Ashley Waller, Esq., Benham Court, Newbury, Berks. Mr. William Bowell, for upwards of twenty years in charge of the gardens at Stawell House, Richmond, has been appointed gardener to Robert Harris, Esq., Shiplake Court, Oxfordshire. Mr. John Shute, late foreman at Palmerstown, Straffan, Co. Kildare, has been appointed head gardener to Mrs. Daly, Hazlebrooke, Dublin. Mr. John Wright, foreman in the gardens of G. T. Clarke, Esq., Talygarn, South Wales, has been appointed head gardener to Allen Sarle, Esq., Green Hayes, Banstead, Surrey.

— **EALING, ACTON, AND HANWELL HORTICULTURAL SOCIETY.**—This Society has recently changed its title, and for the future it will be known simply as the Ealing Horticultural Society. The exhibitors at its shows in the future will be residents within the parish of Ealing. The summer Exhibition will take place on July 9th, and the autumn Exhibition on November 5th, and during the end of July a children's flower show will take place. Mr. Richard Dean, who has held the office of Hon. Secretary for a period of fourteen years, has retired through pressure of other work, and is succeeded by Messrs. J. A. Dawes and Geo. Cannon as joint Secretaries. Mr. R. Dean will remain as a member of the Committee, and give his assistance to his successors.

— **THE WEATHER IN YORKSHIRE.**—Writing on February 28th, a correspondent observes:—"Yesterday about 4 inches of snow fell, and to-day we have another slight fall, but the sun and wind have dispersed much of it. The cold weather is very beneficial in retarding the fruit trees. Peaches and Apricots are crowded with fruit buds. Apples and Pears are also promising well, but Plums are likely to be very partial. Small fruits are very promising, and although we have passed through a very mild winter, it is by no means an early season."

— **THE WEATHER.**—On the 1st of March we registered 12° of frost. The day was bitterly cold with a keen north-easterly wind. Snow fell during the day to the depth of about 2 inches, barely enough to protect vegetation. The frost has been persistent and somewhat severe, as follows—2nd, 14°; 3rd, 17°; 4th, 20°. The ground was so hard that outdoor garden operations were practically at a standstill. On the 4th the wind veered to south-west, with a falling barometer and a slight rise in the temperature.—G. R. ALLIS, *Old Warden Park, Biggleswade.*

— **MR. O. KING, Ray Park Cottage, Maidenhead,** desires us to announce that the annual show of the MAIDENHEAD HORTICULTURAL SOCIETY will be held on Thursday, August 14th, 1890.

— AN appendix to the "KEW BULLETIN" FOR 1890 just issued consists of a list of seeds of hardy herbaceous plants, trees, and shrubs saved in the Royal Gardens, and available for exchange with other botanic gardens. Thirty-two pages of names of plants in double column are given, with the authorities and the native countries in most cases.

— **NARCISSUS AJAX PALLIDUS PRÆCOX** flowered with me on the 24th February. The next of the Daffodils to flower will be *N. scoticus*

or *N. minor*. I have not found the reputed early variety of *N. pallidus præcox*, named *Asturicus*, to be so early in flower as the type, although growing within 9 inches of each other. *N. p-p. Blond Doré* I only received last year, so that I did not expect to be able to compare it with the type this season, so far as regards early flowering. What is the general experience of your readers regarding this point? As regards refined beauty I think *Asturicus* superior to the type.

— **PRIMULA CASHMERIANA** has been in flower on a south border since the middle of December. From a group of some ten plants I have always had some in bloom. It is perfectly hardy here in all positions, and is very pleasing with its large head of deep violet flowers. The thick covering of golden farina on the stems and under side of the leaves adds greatly to the beauty of the plants. It is much finer than *P. denticulata*, which it greatly resembles, but which among other points of difference lacks the farina on the leaves.—S. ARNOTT, *Kirkcudbrightshire.*

— **THE total RAINFALL AT CUCKFIELD, MID-SUSSEX,** during February was 0.92 inch, being 1.40 under the average. The heaviest fall was 0.44 inch on the 15th, rain falling on seven days. Highest shade temperature was 48° on the 18th; lowest 26° on 28th. Mean maximum shade temperature 41.2°; mean minimum 32.0°; mean temperature 36.6°. According to old partial-shade readings it is 2° below the average. Fruit buds in a forward state; Crocuses in full bloom. Land in fine condition for early crops.—R. INGLIS.

— **THE annual report of the OXFORD CARNATION AND PICOTEE UNION** has just been issued, and the published list of subscribers shows that there were 380 members to the end of 1889, and of these 104 became members during the past year. The annual subscriptions amount to £155 9s. The report contains a full statement of the official awards and proceedings at the exhibition held in Mr. Dodwell's garden, Stanley Road, Oxford, August 1st, 1889, giving a full list of all the winning flowers and their exhibitors. Not the least interesting item of the report is a retrospect of 1889 by Mr. Dodwell, in which many of the grand newer yellow ground, self, and Fancy varieties are alluded to, and these by "leaps and bounds" are fast rising in public favour, for they are very beautiful and generally possessing good constitutions, and the Oxford Exhibition is the place to see them in their beauty and extent of varieties.—D. S. H.

— **WIREWORMS AND OIL CAKE.**—I can find no good trap for catching the wireworm, and have therefore given some time to the keeping of this pest. I find that they will leave Potatoes and other vegetables, but the safest trap is oilcake. I therefore put pieces of cake in an old hothouse which was infested with every kind of pest, and it is no exaggeration to say that I caught thousands of worms. I did not write to the Journal, thinking, perhaps, that it might have been found out by someone else. Would you inform me whether this is the case or not? It is quite new to many large Kentish growers, who think it a splendid idea.—A. WELLS INGRAM. [The idea is not new, but the experience communicated is, all the same, worth recording. It has long been taught in books that wireworms eat oilcake till they burst. Some that we have tried did not, and our correspondent makes no mention of the phenomenon.]

— **SCENTED FERNS.**—The article quoted from the London daily papers was very interesting to read, but whether the *Drynaria Willdenovi* is hay-scented or not I am unable to say, never having cultivated it. I have, however, cultivated *D. coronata*, *D. quercifolia*, and *D. diversifolia*, but never detected any smell of hay about them. These three are well worth growing for ornament and variety, especially for large baskets or trunks of trees. There is, however, a beautiful little Fern that is distinctly hay-scented, *Cheilanthes odora*, especially in the partially withered fronds. A plant was brought from the south of Europe to me some few years ago. It lived for a few years, but for want of a suitable house to cultivate it in it gradually died. It would not do in an intermediate stove or in any airy greenhouse, neither is it sufficiently hardy to be placed outdoors where there is much frost, but I should say that good plants may be found in a house similar to one at Kew, where cool half-hardy Ferns are grown in a still and quiet atmosphere, and not having much fire heat. Another plant, although not a Fern, when cut and partly withered, has the scent of new-mown hay. It is the *Asperula odorata*, Sweet Woodruff, a common plant in many gardens, and has pretty white flowers in May and June. It grows very well under trees or in rockeries, and once planted takes care of itself.—A. HARDING.

— **THE GARDENERS' ORPHAN FUND.**—The usual monthly meeting of the Committee took place at the "Caledonian Hotel," Adelphi, on Friday, the 28th inst., Mr. George Deal presiding, there being a good attendance of members. The minutes of the last meeting having been read, a letter from Mrs. Wildsmith of Heckfield, thanking the Committee for their vote of condolence with her on the death of her husband, was also read. Among the special donations handed in was one for £15 from Mr. William Robinson, and from Mr. J. Hughes, the active local Secretary at Birmingham, came the sum of £14 11d., and Mr. J. Hussey, Haines Hill, Twyford, local Secretary for that district, sent £2 16s. The matter of the annual Floral Fête was then considered, and a letter was read from Mr. J. Bourne announcing the willingness of the Duke of Bedford that the Floral Hall be again used for the purpose. It was unanimously resolved that a meeting of standholders and growers be called at the "Hummums Hotel," Covent Garden Market, on Friday, the 15th inst., at 9 P.M., to solicit their co-operation, and appoint a Committee from their body to work in conjunction with the Committee of the Fund. It was also resolved that, agreeable to the convenience of the President and the engagement of the Hall for the purpose, the annual meeting of subscribers, the election of children to the Fund, and the annual dinner take place at the Cannon Street Hotel on Friday, July 18th. The Hon Secretary having brought up a statement as to the probable income of the Fund for the current year, and the sum available for allowances to children after funding the donations, &c., as prescribed by the rules, it was unanimously resolved that ten children be placed upon the Fund at the annual election in July next. The usual vote of thanks to the Chairman closed the proceedings.

— **MANCHESTER FIELD NATURALISTS AND ARCHÆOLOGISTS' SOCIETY.**—A Committee of the members of the above Society has been appointed for the purpose of promoting the planting of trees and shrubs in Manchester and its immediate suburbs, especially in available "open spaces." The idea is approved by the Corporation, and we understand that in addition to the good work already accomplished under their influence in the public parks, &c., evergreen shrubs, planted in boxes or tubs, will before long be placed in some of the principal squares. Every one who cares for the improvement of the town by means of tree planting will gladly support the Corporation and the Field Naturalists' Committee above mentioned. The opinions of experienced practical men are earnestly desired; will you therefore be so kind as to co-operate in regard to the excellent design in hand by supplying information? Information is particularly desired in reference to the different districts of the town. What is best for the north side? what for the south? and so forth. When all possible information has been obtained it is intended to publish it in pamphlet form as a general guide for tree planting and culture, so that every encouragement may be given to those interested in the improvement of the appearance of our city. A form is sent with the following questions:—"What trees would you recommend for open spaces?" "What kind of shrubs, especially such as would succeed in tubs or boxes?" "What suggestions can you offer as to soil, treatment, and upon any important point relating to tree culture in towns?" Answers to these queries should be addressed to Mr. C. J. Oglesby, 16, Kennedy Street, Albert Square, Manchester.

— **PLANTING AND PRUNING FRUIT TREES.**—I have been planting some fruit trees to-day which have been laid-in during the winter. Of course it is very late for such operations now, but we often have to do things from force of circumstances. If any amateur has neglected to plant his trees I advise him to set about it at once, for I find root action has commenced freely, and the white feeding fibres are bristling from the thick roots. In such cases as this the trees should be moved as speedily as possible, for half an hour will parch the tender roots. If they do get dry, take care to damp them before putting them in the soil. Plant firmly, and do not forget to mulch the surface with long manure, for this will be very beneficial to the roots. Do not be afraid of cutting-in the head or branches of the tree, for the roots have been curtailed in digging the tree up and in its removal also. An argument was raised early last year by some of our authorities on this subject, some advising to prune back severely, while others said, Leave the head intact. Now I am an advocate of the old adage, "The proof of the pudding is in the eating," so, after reading the various opinions on the subject, I formed my own, but determined to test the matter in a practical way. I had planted several young trees, so I went over half of them and pruned them pretty hard, while the others I left to take care of themselves. At the present time I do not require any further proof as to the best method. To confess the truth, I have just lost a year with the trees

I left unpruned. There is nothing like learning by experience. I have now pruned the whole of them. If any amateur would like to dive into this subject, he cannot do better than study "Profitable Fruit Growing." I do not care how wise he may be on the subject, he will be wiser still after its perusal.—EXCELSIOR.

— **THE WEATHER IN FEBRUARY.**—The past month here has been noted for the small amount of rain which fell compared with that of February, 1889. The total amount for last month being 0.71 inch, being 1.35 inch less than fell February, 1889. Rain fell upon five days, the maximum in twenty-four hours being 0.33 inch on the 15th, minimum being 0.03 inch on the evening of the 5th. We registered some frosts nearly every morning, but nothing very severe except on the 28th, when 10° were registered.—E. WALLIS, *Hamels Park Garden, Buntingford.*

— **THE usual fortnightly meeting of the READING GARDENERS' IMPROVEMENT ASSOCIATION** was held on Monday evening last, a large number of members being present. R. D. Catchpool, Esq., presided, and Mr. J. P. Jones gave a lecture on "The Use of Flowers." He said gardeners should be the most punctual, patient, persevering, and happy men. He described the use of flowers in various ways, showed illustrations of table decorations as used recently in Japan, and referred to the culture of flowers in the south of France for perfumes. The fertilising of flowers by the different insects was also dwelt upon, as well as its importance in continuing the various races of flowers. A vote of thanks was unanimously accorded.

— **TOO SUCCESSFUL EXHIBITORS.**—No doubt the above subject is one that all who have to take part in the management of cottagers' shows have to contend with, and to explain reasons to disappointed exhibitors and their friends and sympathisers. My experience of cottagers' shows and the inspection of cottagers' gardens is that the most industrious and painstaking men get the most prizes, and so they ought, for to grow a good collection of useful vegetables of good size and quality in the spare time a man may have after his regular day's work is done, or before it begins in the morning, means a good deal of hard work, and many hours profitably spent. Of course there are in most communities a few schemers who try to get at the same result in a different way, but as a rule they are soon found out. We have found it necessary in our case in some of the competitions to make classes for those engaged in garden work, as well as classes for ordinary cottagers, farm labourers, &c., as it is found that men employed in gardens show greater aptitude than ordinary labourers. I quite agree with your correspondent Mr. Raillem, page 119, that at the time the prizes are distributed one of the judges, or someone competent to speak, should give a few words of encouragement to the unsuccessful exhibitors, telling the means to use to win next year, or in some way fairly (to use a racing term) to handicap the winners; but with fair play and no favour the best man should always win, and anything that interferes with that principle would not be to the advantage of any society or community. With regard to improved Blackberries, in "Notes and Gleanings," recently, I am made to say that a Bramble in 1889 made a shoot 3 feet long; it should have been 30 feet long.—R. MAHER, *Yattendon Court.*

— **NICOTIANA AFFINIS IN THE CONSERVATORY.**—I cannot say whether my experience with this is peculiar, but certainly I am in a position to very warmly commend it, as can be gathered from the following details. A London firm sent me a few seedlings, with other plants, about this time last year, telling me they thought the strain more dwarf and sweet-scented, and almost perpetual flowering, asking me to give them a trial. A 12-inch seed-pan was the next to hand in the potting shed, and into it they went. The pan was shallow, with comparatively much drainage and little soil, and possibly intended for something else. I determined if the three plants did well I would feed them with liquid manure. This may possibly account for their coming into bloom in about a month, and flowering continuously since up to the present with this treatment. The first blooming was over in the autumn, but the old plants seemed healthy. I removed two and left the centre one, cutting it down to within 3 inches of the soil, as I saw some eyes further down. I commenced gradually feeding with a concentrated liquid manure of soap-suds, fowl manure, soot, &c., mixed according to the stage of growth and time of the season, with warm water from the conservatory cistern as growth and flowering progressed. Almost immediately growth, shoots, and flowers showed, and during the whole winter it was delightful to sniff the delicious scent every evening I strolled into my conservatory. Should you think it possible the strain is better than that usually grown, I can send you a flowering spray to

see. My plant seems still to have a floral career of months before it.—
W. J. MURPHY, *Clonmel*.

— *PRIMULA VERTICILLATA*.—This is a lovely member of a large family, and well worthy of being more extensively cultivated than it is at present. Treated as a hardy species its true character is not fully developed, for, although interesting amongst its congeners in the rockery, stormy weather spoils many of the more tender beauties which help to make it so pleasing and attractive as a pot plant. The slender, graceful spike coated over like the "Dusty Miller," rising out of its bed of leaves, each one covered in the same manner, always attracts attention, and as whorl succeeds whorl of pale yellow flowers, the effect of a well bloomed plant is charming. Seed sown now and put in a warm place until up, then grown in a cool, airy position free from chilly currents of air, will make most useful sized plants by this time next year. They prefer a light porous soil to grow in, and ought never to be watered over the foliage, as the water lodges in the axil of the leaves and causes the plants to damp off. Damp appears to be the only enemy to be guarded against, and if this can be prevented and a suitable position accorded them they are remarkably easy plants to cultivate. After the flowering period they ought to be gradually hardened off, and finally planted outside, to be lifted again in the autumn before being damaged by frost, and wintered on vacant Strawberry shelves or other suitable place until bloom appears, when they might be removed to the conservatory or wherever required. They can be grown for many years in this way, but for general purposes it is not advisable to grow them for more than about three years, as young plants are far more serviceable than old ones; the latter can be planted in an elevated position in the rockery or alpine garden, where, as previously stated, they form interesting objects.—M. D.

— A COMMITTEE has been formed in Paris for the purpose of making arrangements for the erection of a statue of the late M. BOUSSINGAULT. His work marked an era in the history of the agricultural sciences, and we have no doubt there will be a prompt and liberal response to the Committee's appeal for subscriptions. M. Pasteur is the Honorary President of the Committee. The acting President is M. Schlösing, and the following are the Vice-Presidents:—MM. Berthelot, Duchartre, Laussedat, Peligot, Risler, and Tisserand. MM. Müntz and Sagnier are the Secretaries, and M. Liébaut is Treasurer.

— THE Calcutta Herbarium contains a rich collection of MALAYAN PLANTS, and Dr. King, the Superintendent of the Calcutta Royal Botanic Garden, proposes to publish from time to time a systematic account of as many of them as are indigenous to British provinces, or to provinces under British influence. In addition to the States on the mainland of the Malayan peninsula these provinces include the islands of Singapore and Penang, and the Nicobar and Andaman groups. The classification which Dr. King intends to follow is that of the late Mr. Bentham and Sir Joseph Hooker.

— FOR the purpose of growing plants under more NATURAL CONDITIONS than those usually afforded by the soil and surroundings of ordinary botanic gardens, M. G. Bonnier, the Director of the Botanic Garden in Paris, has obtained from the Director for Higher Education in Paris the grant of a piece of land in the Forest of Fontainebleau, as an annexe for experimental culture. It has been placed under the special charge of M. Cl. Duval.—(*Nature*.)

METHODS OF JUDGING.

It seems my suggestion at page 118 does not meet with the approbation of Mr. G. A. Bishop (page 176). Perhaps I do not understand him in the points he puts forward, while I am also of opinion he does not understand me. I certainly do not agree that he has solved the problem to the satisfaction of everyone; on the contrary, I suspect his method would increase the difficulty. I have repeatedly seen the verdict of judges questioned and criticised. I have accompanied judges often while adjudicating at horticultural shows, as well as having acted as judge, and not seldom we were placed in a difficulty how to decide; and more than once, so near were the competitors, that I have witnessed the judges toss a penny to decide which was to get the first honour. Now, in all fairness, would it not be better to divide the prize money nearly equally in such cases? Personally, when I had a difficulty to deal with I endeavoured to discover coarseness, and anything possessing it was laid aside; still I have often witnessed some prominent defect, but the other properties far outweighed that, and entitled it to the first prize, taking everything into consideration. Whatever may be the opinion of others, mine is that the total amount of prize money for three prizes should be divided by the judges according to the merit of the

articles competing. To withhold all first prizes above a certain number would be a death stroke to the advance of horticulture as well as to exhibitions. Does not Mr. Bishop's last sentence stultify his first, and suggest that his proposed system is faulty? because "if the losing of first prizes is not sufficient to move the hinder ones they are not worthy of taking honours others are entitled to." Does not that quotation support my argument?—WM. THOMSON, *Blantyre*.

DENDROBIUM MACFARLANEI.

IN your notes accompanying the faithful representation of the above Dendrobe in your last issue, mention is made of the plant that flowered in Chalfont Park a few years since, some particulars of which may be interesting. The plant was brought over and given to me, with others, by a friend then connected with a steamship company trading between this country and Queensland, and the Orchids he collected from one of the islands lying in their route off the Australian coast. He had no knowledge of plants himself, and brought them as curiosities. They had only been tied up in canvas. He arrived in London November 4th, 1884, and the bundle of Orchids reached me about three weeks later.

The plants were cleaned, some potted in crocks, and some suspended in an intermediate house, and thence transferred to the stove. About twelve months after, early in December, 1885 (not autumn, 1886, as stated) the subject of this notice produced an erect raceme of five flowers, the latter keeping fresh and good over two months. Unfortunately it was not thoroughly established, and did not long survive the flowering. My friend ceased travelling that route, but obtained for me from an acquaintance there another importation; but although I forwarded a dry pseudo-bulb of *D. Macfarlanei* as a specimen of what I wished to obtain, I only received one plant anything like in growth, and possibly this may prove not to be that variety. It is well established, and from its appearance I had hoped it would have flowered this spring. Of this last importation some have proved botanical curiosities only, but I have several well-established plants of a rather strong growing Dendrobe that I have not yet been successful in flowering, and another with a short pendulous pseudo-bulb, showing flowers which will open shortly.—C. HERRIN, *Dropmore Gardens*.

DENDROBIUM NOBILE AND CALANTHES.

THE enclosed is a portion of a pseudo-bulb cut from a plant in an 8-inch pot, and is a fair sample of the others as regards the number of flowers. Fourteen dozen flowers were cut from a plant in a 9-inch pot on February 27th, and by taking a few plants into the stove every fortnight the supply lasts for two months. *Calanthe Veitchi* and *vestita* are successfully grown, the former having pseudo-bulbs over 1 foot high. They are most useful for house and table decoration. Perhaps a few particulars respecting my system of culture for both the *Dendrobium* and *Calanthe* might be useful to the young readers of your widely read Journal.—J. C. H.

[The pseudo-bulb sent was a strong one, with sixteen fine flowers, and your system of culture would be gladly recorded.]

CYPRIPEDIUM ELLIOTTIANUM.

AT the end of October, 1888, Mr. Godseff sent me a flower of a new *Cypripedium* from the Philippine Islands, which it was desired should bear the above name. Unfortunately the flower was damaged in transit, and its true character could not be determined; however, a note written respecting it appeared in the *Journal of Horticulture* on November 1st, and this was, I believe, the first published reference to one of the most handsome *Cypripediums* yet introduced. Messrs. Sander & Co., St. Albans, were the fortunate possessors of the plant, and through them it has been brought into prominent notice during the past year.

C. Elliottianum partakes of the character of *C. Rothschildianum*, and some have gone so far as to consider them identical, but the decision of the Orchid Committee of the Royal Horticultural Society at a recent meeting gave an official endorsement to the opinion of Reichenbach and other authorities as to their distinctness. From Mr. H. M. Pollett's plant exhibited at the meeting named—i.e., on February 11th, when a first-class certificate was unanimously awarded for it, the woodcut (fig. 28) has been prepared, and shows both the floral form and the bold markings clearly and accurately.

The dorsal sepal is broad, oval, white, with rich maroon stripes extending from the base to the apex, and their regularity in breadth and distance apart gives a striking character to the flower, the lower

Veitch & Sons' "Manual of Orchidaceous Plants," but that appears to be a quoted description contributed by Mr. James O'Brien to the *Gardeners' Chronicle*. I have seen some others similar to Mr.

FIG. 28.—CYPRIPEDIUM ELLIOTTIANUM.

sepal being similarly marked but necessarily less noticeable, as it is partly hidden by the lip. The petals in the specimen exhibited were faintly straw tinted, but they are described as white in Messrs.

Pollett's specimen, but the tinting may possibly be due to age, a change of this kind being common in Orchid flowers. The ground colour is of little moment, however, for the chief beauty of the

petals rests in the deep crimson maroon spots so freely yet regularly scattered throughout the greater part of their length, the basal half in particular. The margin also bears a number of dark rather long hairs, and the petals taper gradually from the base to the apex, varying in length from 4 to 6 inches. In the first flower I saw they were only $3\frac{1}{2}$ inches long. The lip has a remarkable resemblance to *C. Stonei*, the rosy veining and tinting being perhaps a little more strongly marked.

The plant is of strong growth, and evidently free flowering, as shown in the illustration, but some of the collected specimens had five flowers on a stem. The leaves are long, broad, and bright green, the whole habit of the plant indicating a vigorous constitution. It will probably be easy of increase and culture, and will be prized wherever *Cypripediums* are admired. The name was bestowed in honour of Mr. Elliott of New York.—LEWIS CASTLE.

VALUE OF CALANTHES.

THERE are more brilliant and innumerable choicer Orchids in cultivation, but in point of general utility and effect it may fairly be assumed that *Calanthes* stand pre-eminent. This may appear a somewhat bold assertion, but I think I can prove the truth of my words. In the first place they are at their best any time during December, January, and February (I am alluding solely to *C. Veitchi* and *C. vestita*), they can be utilised in many positions with excellent effect, and they remain fresh and bright for several weeks, the period naturally varying according to circumstances; added to this they are not expensive, being also easily increased, and not difficult to cultivate. A back shelf or a suspended shelf, not far from the glass in each case, in an ordinary plant stove or forcing house suits them admirably, and with fairly skilful treatment the pots become crowded with roots, stout growths, gradually developing into fine flowering pseudo-bulbs. *Calanthe* foliage is coarse and unattractive, but fortunately this ripens and falls, or is removed some time before the flower spikes are far advanced in growth, this admitting of their being most effectively grouped with various other plants. We annually flower upwards of 200 bulbs, and the greater portion of these are interspersed among Ferns, principally *Adiantums*, as they come into bloom. As a rule they are at their best with us somewhat late in the season, or at the end of January, when the photograph taken of some of them and sent with this to the Editor of the *Journal of Horticulture* was taken. The temperature of this house or fernery as a rule ranges from 55° by night to 65° in the daytime, and this suits *Calanthes* when in flower better than either higher temperatures accompanied with more moisture or an ordinary greenhouse heat, spotting and damping quickly resulting when the *Calanthes* are submitted to either extreme. *Calanthes* are especially valuable for house or room decoration, and if not damaged in transit do not suffer much in comparatively warm dry rooms for a few days. The *C. vestita* varieties are particularly effective with Maidenhair Ferns on a mantel shelf, and associated with *C. Veitchi* in stands and groups generally give an excellent finish to these. Undoubtedly the pseudo-bulbs of the "dark" or most richly coloured forms of *C. Veitchi* are pecuniarily of more value than *C. vestita*, but I attach the most value to the latter.

Effective as are the spikes of *Calanthes* in groups, they are even more serviceable in a cut state. A few hours out of water on the cloth of a dining table does not injure them. I have frequently used them in that way, and they are singularly well adapted for vases generally. The less, however, they are mixed with other flowers the better, the spikes of *C. Veitchi* meriting a vase with a base of greenery to themselves. Those who may have their doubts about the effective appearance this species alone presents in a cut state ought to have seen the dining table at Canford Manor as prepared by Mr. T. H. Crasp, Lord Wimborne's gardener, on the first night of the visit of the Prince of Wales during the third week in January last. No less than 150 spikes of *Calanthe Veitchi* were used, these being distributed over about fourteen rather large and flat silver vases. Eight of the largest vases containing the finest spikes were arranged through the centre of the long dining table, twelve smaller ones with shorter spikes alternating with the dishes of dessert. In each case a rather heavy mass of fine fronds of Maidenhair Fern occupied the base of the vase, the *Calanthes* springing from these in a bold and free style. Two Kentias and about fifty bunches of Marie Louise Violets, the latter in small fish globes, completed this most effective table. Fairly compact spikes of *C. Veitchi* are suitable for ladies' wear, but the most serviceable and attractive sprays are best made by wiring each single flower, a mass of these 3 inches to 4 inches wide and about 8 inches long, backed by fronds of *Adiantum*, being difficult to surpass. The ladies of the Royal party at Canford Manor were furnished with sprays thus formed on the night the *Calanthes* were used for table decoration. Spikes of *vestita* are very effective in hand bouquets and

wreaths, and in sprays backed by coloured or prettily veined Ivy leaves are even more attractive.—W. IGGULDEN.

[The photograph shows an excellent group of *Calanthes* and Ferns, but the details are too numerous and the size too small to admit a satisfactory reproduction as an engraving.]

ORCHIDS AT THEDDEN GRANGE, ALTON.

As I was privileged a few days ago to see the Orchids at Thedden Grange, I thought a few notes may prove interesting to the readers of the *Journal*. Till within the last two or three years Orchids had not been so extensively grown here as they are now. J. G. Wood, Esq., the owner of this beautiful garden, takes a lively interest in these plants, to which special attention has been directed by the gardener, Mr. Campany, and judging from the general appearance and health of the plants his attention has not been in vain. The old *Cœlogyne cristata* seems to be specially well grown; thirteen plants were in flower, one in a 12-inch pot, with sixty-two spikes and over 300 flowers. Nine of the plants were doing duty in the mansion, and had been there for a month, and at the time of my visit it was a sight not to be easily forgotten. Among those in flower were the following:—

Arachnanthe Clarki, recently figured in "*Bot. Mag.*," 7077; *Dendrobium Ainsworthi*, *D. aureum*, *D. Brymerianum*, *D. crassinode*, *D. densiflorum*, *D. Farmeri*, *D. fimbriatum oculatum*, *D. Devonianum*, *D. Pierardi*, *D. Pierardi latifolium*, *D. primum*, *D. giganteum*, *D. nobile*, one grand plant in a basket with 103 flowers; *D. sulcatum*, with eight racemes of eighty-seven blooms; *D. Wardianum*, a fine variety, with pseudo-bulbs 38 inches long, splendidly flowered; *Odontoglossum Alexandræ*, *O. cordatum*, *O. Cervantesi*, *O. Andersonianum*, *O. Harryanum*, *O. maculatum*, *O. Pescatorei*, *O. Rossi majus*, thirteen plants; *O. Rossi majus roseum*, *O. Roezli*, *Cattleya Walkeriana*, *C. Trianae*, *Sophranitis grandiflora*, *Oncidium sphacelatum majus*, 266 flowers; *O. carthaginense*, *Lælia anceps*, a well-flowered specimen of a good variety; *Masdevallia Lindenii*. Among those showing flower were *D. Devonianum*, *D. densiflorum*, *D. transparens*, *D. thyrsiflorum*, *D. suavissimum*, *D. Deari*, *D. draconis*, &c. Other plants are equally well grown at Thedden.—H. COSTER, *Froyle Park Gardens*.

BRUSSELS SPROUT.

I FULLY endorse what is stated on page 169 by Mr. Thomas respecting this choice vegetable. How many varieties—or rather names of it—are now to be found in the various catalogues with eloquent descriptions as to merits, yet when grown, owing to their monstrosity, are fit only for cattle? I have grown some such where there was 12 or 18 inches clear stem from the ground to the first formation of sprouts, the few which then formed being large and coarse. Where a good strain is grown and due attention paid to cultivation, no vegetable is more profitable in winter, either for a gentleman's table or market purposes. This I have proved for several years with the strain I grow. I send you a sample (which is only moderate) as showing the character of the variety that has never failed to give satisfaction. I always sow in the open ground about March, planting when about three rough leaves are formed into their permanent quarters in rows 2 feet apart.—T. B., *Leeds*.

[The sample sent is excellent, the side growths being medium size, firm, and crowded on a length of 18 inches of stem. It closely resembles specimens that were sent to one of the meetings of the Fruit and Vegetable Committee of the Royal Horticultural Society by Mr. A. Harding of Orton Longueville, and for which we think he was awarded a cultural commendation.]

GARDENERS OUT OF SITUATIONS.

I SINCERELY thank all gardeners who have given their views in the *Journal of Horticulture* respecting gardeners out of situation. I should be pleased to join any properly formed society that would assist in this matter, but doubt if such a society as is said to exist at Belfast could be of much help. The question is, Would employers apply to such a society for a gardener? I fully agree with "B." that advertising is one of the best modes of getting a situation; that is to say, when you have not a friend to push you in. Could not something be done by a self help society to make arrangements with some of the leading horticultural papers, and pay so much a year? then when any deserving member who has been in a place for two years and leaves with a good character, get permission to advertise two or three times in the usual way, and save him paying what is charged in the ordinary way? Perhaps some of your readers may be able to say what such a society should be, and how to proceed better than I can.—ANGUS MCKINNON, *Machen House, Newport, Mon.*

[We hear that a project of the nature suggested will shortly be considered by a responsible body with the object of determining its probable usefulness and practical working. If any of our readers have any definite propositions to submit they shall be placed in the hands of a Committee that will have the subject under consideration. Vague

generalities will not suffice, and it is highly desirable that the methods proposed be such as will merit the good-will and confidence of the affluent who require the services of gardeners of proved respectability and competency. We think it advisable not to insert any more letters on this subject at present. Any that reach us on or before next Monday morning will be placed in the hands of men in sympathy with the object in view, and who are at the same time not without experience in organisation].

YOUR correspondent "R. M." says, "I hope that the day is not far distant when a system of national insurance for workers will be inaugurated on the same principle as that which has recently become law in the German Empire." I have studied this problem of self-help and dependence for some years, as practised by our large friendly societies in this country, therefore I was much interested in this colossal German scheme, but after reading and carefully studying its lines, honestly own that to my limited vision, when compared with our own voluntary societies, its so-called great advantage vanishes.—A. C., A.O.F.

MODERN CHRYSANTHEMUM CULTURE.

I MAY be considered a very feeble defender of the Chrysanthemum, not being a very important grower, yet I rank amongst the oldest, having taken "the fever" in a mild form when living at Calderstone in the days that Mr. Broome came from the Temple Gardens to St. George's Hall, Liverpool, to show his trained plants and teach their culture. Unfortunately most gardeners at the present time are carrying the "last straw" in connection with labour, consequently have none to waste in cultivating that which is not really required; and in common with many other gardeners I have not yet met an employer who looked upon the Chrysanthemum with any special degree of appreciation, therefore have not had the inducement to sacrifice the more important occupants of the gardens for the sake of the Chrysanthemum. Neither have I seen traces of others doing so, but have seen several instances quite the reverse, as may be found at Impney, Heckfield, Parkfield, Trentham, and many other places famous not only for the Chrysanthemum, but where everything else were correspondingly well done. The above may partly relieve Mr. Thomson of his anxiety in this respect.

I may now confirm his remarks respecting the cutting down system, which will doubtless become more general when so successfully practised in gardens such as Trentham and Drumlanrig. At the former place last autumn I was much impressed with the beauty and usefulness of many sorts grown in this way. In my opinion it is yet much the best way to propagate the tops of the taller varieties just as they begin to form crown buds where dwarf decorative plants are required with large blooms, as unfortunately it is only the moderately dwarf sorts that flourish on the cut down system, and I really fail to see any objection to a few dozen twelve-footers in the Peach house of every garden, as decidedly the most beautiful blooms are produced from these in such varieties as Belle Panle and Madame C. Audiguier. Where these are objected to a capital selection not exceeding 3 feet high can be had with Avalanche, Stanstead White, this latter we had 14 inches in diameter and kept in prime condition two months last year. For colour Edwin Molyneux, M. Freeman may be chosen with Val d'Andorre, L'Adorable, Mrs. Falconer Jameson, Madame John Laing and Sarah Owen. For incurved flower all the Teck family are the best—Lord Eversley a beautiful long-keeping white; Norman Davis, yellow; Princess Teck, blush; Charles Gibson, bronze; and Hero of Stoke Newington, rosy blush. Some of the Anemones are also dwarf, producing handsome useful blooms in almost every shade of colour.—J. H. GOODACRE.

THREE GOOD LATE-FLOWERING VARIETIES.

I HAVE had plants of most of the generally recognised late flowering varieties this season, many of them producing good blooms, but none amongst them is so conspicuously good and so effective as the three following, all of which are comparatively new and not generally known, nor are they included in catalogue lists of late-flowering varieties.

Putney George.—Judging by its character with me this season, this is a long way ahead of all other dark coloured varieties for flowering in January. The habit of the plant is very robust, with ample leafage, scarcely at all liable to mildew, and the buds open freely, however late. It also lasts well for a long time, and does not when old take on a dull dead tint as do King of Crimsons, Cullingfordi, Julie Lagravère, and some other varieties. Its colour—brilliant crimson with gold tips to the florets, and bronze striped back—is wonderfully effective at Christmas time, and in the market finds ready and eager purchasers.

Mrs. T. H. Spaulding.—This is an American variety of 1888, producing large blooms, pure white, excepting only for a tinge of lemon colour at the base of the florets. Earlier in the season the florets incurve somewhat after the manner of Pelican, but late blooms pro-

duced now reflex, and the broad ribbon-like florets are flattened out, adding materially to its effectiveness when cut for making up into sprays or wreaths. Of a similar character to this, but not quite so pure in colour or good in form, is Lady Lawrence, syn. Mrs. Beale.

Mrs. Dunnett.—The last of my trio is Mrs. Dunnett, a variety introduced by Messrs. Carter & Co. two seasons ago. It is a large cup shaped flower with long quilled petals; white, delicately flushed and shaded with soft rose pink—a pleasing combination of colours. The plant is only a moderate grower, with rather small foliage, which is bright, smooth, and hard, lasting well on the plant and little subject to mildew.

I intend during the next season to grow a number of plants of each of the varieties named specially for flowering at Christmas and in the following weeks, and I can confidently recommend others to do the same who wish to have good blooms of effective varieties.—W. K. W.

CHRYSANTHEMUM MR. W. W. COLES.

THE engraving on page 111 of the Journal of this new Japanese shows to the best advantage a grand variety. From what I know it is an excellent "keeper," which is a decided gain. A bloom grown by Mr. T. B. Morton, Darlington, was shown by him at the Centenary Exhibition in Edinburgh, where it stood three days, and afterwards was good enough to take premier honours as the best Japanese bloom in the show at Pontefract. I understand that the stock is very limited at present, which is to be regretted. Those who are fortunate enough to obtain it I would advise to grow it well, and I think they will then have reason to be thankful.—E. MOLYNEUX.

OPEN AIR CHRYSANTHEMUMS.

SELDOM have Chrysanthemums done so well in the open air as during the past season. The plants during the summer grew strongly yet sturdily, and the well-matured branches flowered exceptionally well. Added to this the weather in November was most favourable to the opening and durability of the flowers, and in some instances quite a gorgeous display was the result. Not only were the old and well-tried favourites beautiful, but other old and newer varieties not often seen good in the open air were both serviceable and showy. As a rule the preference ought to be given to the early, or what are known as summer flowering varieties, and those among the earliest to flower of the sections most generally grown in pots. Not unfrequently old plants are depended upon either from choice or indifference, but, as a rule, early raised young plants give the best results. A mass of shoots springing up from a strong old stool only serve to weaken and spoil each other, a few poor flowers only being borne on the top of each; whereas if young plants are raised, these being early topped once or twice, a few strong branches are formed on each, these in their turn naturally producing side flowering shoots nearly throughout their entire length. There is no necessity to propagate at this early date, February or even early in March being soon enough to insert the cuttings. What has to be studied now is the source from whence suitable cuttings can be had. If there are no plants of each variety kept in pots and the old stools in the open, the chances are either no cuttings will be preserved from slugs, or else that the points of the young suckers will be crippled by frosts, and fail to strike in consequence. It is therefore necessary to either protect the old stools with a heap of ashes, leaf soil, or cocoa-nut fibre refuse, or else to lift some of each variety and store these in boxes or pots in a cool frame or pit.

Among the earliest to flower, the season commencing in July, are the yellow and white forms of the very dwarf La Petite Marie, Mrs. Cullingford, Précocité, St. Mary, Frédérick Marronet, Fiberta, Hermine, Madame Piccol, Lyon, Mr. W. Piercy, and Alice Butcher. Those which flower late in September, and frequently till cut down by frosts, are Catherine Wermig, Madame Desgrange, Alexandre Dufour, La Vierge, Sœur Melanie, and L'Île des Plaisirs, all being of good sturdy free flowering habit. There are several excellent Japanese and incurved varieties that follow closely, among these being Lady Selborne, James Salter, Lord Beaconsfield, Elaine, Elsie, Margot, W. Holmes, L'Africaine, and Bertier Rendatler, all Japanese; and of incurved, Mrs. G. Rundle, Mrs. Dixon, Mr. G. Glenny, Beverley, Mr. Bunn, Prince of Wales, Lord Derby, Prince Alfred, and Lord Wolseley. The foregoing succeed well in most seasons, and not unfrequently many of the somewhat later flowering varieties in each section do fairly well, especially if given the benefit of a sheltered position. On the whole the Pompons are the most reliable for open air culture, nearly all of these flowering most abundantly, the individual blooms being more perfect than is usually the case with either of the other sections. Such good sorts as Bob, White, Gold, and Lilac Cedo Nulli, Golden Circle, Rose Trevenna, Aurore Boréale, Rosinante, Mdle. Marthe, and Comte de Morny were seen at their best during the past seasons, numerous cottagers, as well as the owners of larger gardens, having a fine display.

COMMENTS AND SUGGESTIONS.

I HAVE been looking through the Journal, and first I note the conclusion Professor Marshall Ward came to respecting the canker in Apple trees (page 178) which I consider a very just one. I came to the same conclusion some time since; hence my letter at the beginning of the year. Since then I have been busy concreting the bottom as suggested, and planting and transplanting about 100 trees of Pears, Plums, and Apples, and shall soon, I hope, be able to reap the benefit from it.

Next as to shelter around orchard fruit trees. I have always been in favour of it, but never before have seen Willows suggested as on page 145. I think that another move in the right direction. I have thought Poplars, Larch, Spruce, and Scotch Firs to be the best for that purpose.

As to associations for assisting less fortunate fellow gardeners, I think the idea is a good one. We see the good of the one at Birmingham, and no doubt in many more places equally as good results might be obtained. These must have the ways and means of helping many if they really are in distress, but as in numerous other societies there are sure to be black sheep, and they make it worse for the more deserving when applying for relief.

I see a fellow gardener asking for means of destroying Yarrow on his lawn. I certainly would advise him to make an exchange. I am sure that it is a useful herb for cows in milk. I have always noticed if any is found on pasture where cows are turned out you will always find that part is eaten off as short as a mowing machine could cut it, and often the grass surrounding the same is left untouched. I should hesitate if I were in his place before destroying so useful an herb.

I am pleased to see a Society of French gardeners has been formed, with the object of establishing more cordial relations between France and England on the exchange principle.

On page 176 is an article on the "Cultivation of the Orchard." If properly manured I do not see any objection to cultivate with vegetables that are off before the crops of fruits require to be gathered. I have seen such light crops as Radishes, Lettuces, Cauliflower, and early Potatoes grown with great advantage and profit to the tenant, and found employment for many hands at a time of year when employment would have been scarce. I always think if a deep trench was cut round each healthy tree, just the circle of the branches overhead, and with every root shortened, would make the trees more fruitful, and consequently more profitable, and allow the ground between to be made profitable without robbing the fruit trees as suggested.

Returning again to the orchards. I have noticed in Kent and other places as well that the best results have been obtained from plantations that have been sheltered from north and east winds, and on ground slightly rising to north, thus having the full benefit of sun south-east and south-west.

I send you these few comments for what they are worth. You can make what use you think proper of them. I can send any amount of specimens of cankered wood if required, not only fruit tree wood but of other trees I have seen growing under the same conditions.—G. C., Warwick.

I INTEND making a few remarks on some subjects which seem to be among the leading questions of the day. The proposal of a Hall for Horticulture is well worthy the support of everybody who takes an interest in gardening. It is far from creditable to the gardening community that the leading Society, to which we all look for guidance in matters relating to horticulture, has no suitable meeting place in London. The proposal which Baron Schröder made at the meeting of the Royal Horticultural Society of Tuesday, 11th February, is one well worthy of support, and I have no doubt it will be supported. We find at the meeting in question over £2000 was promised—truly a good beginning.

LARGE CHRYSANTHEMUM BLOOMS.—It is seldom that Mr. D. Thomson's writings find their way into the Journal. I wish we had more of his sound practical advice. He condemns fishing rod Chrysanthemums, and I hope he will continue to do so. I think Chrysanthemum societies might do a great deal to encourage the dwarfing process. I never could see any beauty in Chrysanthemums trained as standards or on balloon trellises, as the twisted stems give the plants an unnatural appearance. As regards Chrysanthemum societies in England, I find by Mr. Molyneux's able article on the subject, that the majority of them are in a flourishing state. All honour to Portsmouth and other societies, which, after certain hours, allow the industrial classes an opportunity to inspect them at a low price. This is not done in Dublin and elsewhere.

THE ROYAL HORTICULTURAL SOCIETY OF IRELAND.—I am sorry to have to admit that this Society is not in as good a position financially as I desire to see. At the same time I am compelled to ask, What work is it doing compared with what it might do were it placed under the control of an energetic council? Why not have its monthly meetings where papers could be read by some of the leading gardeners in the neighbourhood? Perhaps Mr. McKenna could be induced to tell how he managed to grow the fine Grapes which were the admiration of visitors at the summer and autumn shows? Might we not also have a few words of sound sense from Mr. Bedford, Straffan House Gardens, on how to grow the beautiful Orchids which are such a credit to him? I throw out these few hints, not in any carping spirit, but as a well-wisher of the Society. Anything I can do to assist it I shall only be pleased to do, if the directors bestir themselves and keep abreast with the times. When I find that the charge for admission to all the Society's shows is

half-a-crown, can it be wondered at that it does not pay? Have the artisans of Dublin no taste for such shows, that they should be thus excluded? I think it is full time that the gardeners and nurserymen of Ireland put their shoulders to the wheel and worked together for the good of the Society in question and the general advancement of horticulture. True, of late years the prospect has been anything but encouraging, yet I believe the worst is past, and that there are brighter days in store for our "unfortunate country," as we are so prone to call it.

IRISH GARDENERS.—I find in Mr. Chas. Lewis's paper on Gardening, page 158, the following sentence:—"Irishmen and Welshmen are lagging in the rear." I venture to join issue with the writer of that statement. Perhaps he has not been in Ireland to see for himself, and is therefore not well informed. Having spent the greater part of my life in this country, I think my opinion will carry greater weight than Mr. Lewis's. As regards nationality, give us the same privileges which are granted to English or Scotch gardeners, and I will venture to predict that we will not only hold our own but lead the way. My motto for every young gardener is Nil Desperandum. Let us who hold positions of trust, and who are held responsible for those who serve under us, encourage young men by precept and example to take an interest in their work, encourage sound reading, drawing, and writing—the latter, I am sorry to own, a great many are deficient in.

GARDENERS' BENEFIT SOCIETIES.—I think it would be a very good thing if all the different societies of this nature were to unite. I believe it would answer the purpose better for which they are formed. I am pleased to see on page 160, under the heading of "Gardeners out of Situation," that a correspondent mentions a Society for the relief of gardeners was formed in Belfast. I wish it every success.—R. RUSSELL, Palmerstown.

MANNERS AND CUSTOMS—A CATALOGUE COMMENTARY (Continued from page 180.)

Ophirie (Goubault, 1841).—A strong, long, rapid grower, of vigorous constitution and quite hardy, with abundant but not thoroughly evergreen foliage, having more of the character of the true *Noisette* than any of the *Roses* mentioned in this section. Not very liable to mildew, or to be injured by rain, but almost always comes quartered, which is indeed its normal shape. Only valuable for its quaint coppery red colour, which I have always imagined somehow or other to be the source of that shade wherever it appears in our *Tea Roses*. Not free blooming, but a fair autumnal. The flowers are very small, and the plant is really not with growing, except as a curiosity or from old associations.

Rêve d'Or (Ducher, 1869).—A very strong climbing *Rose*, of most free and rapid growth, fine evergreen foliage, and generally great merit. It has one most desirable piece of good manners as a climber. Other *Roses* of this section and of the *Gloire de Dijon* race are apt, when grown on a wall, to become weak and bare in foliage towards the bottom, so that all the blooms are out of reach, and the plants look unsightly from the naked appearance of the lower portions of the branches. This is not the case with *Rêve d'Or*, and it adds considerably to its value as a climber, that the lower parts of the plant are generally fairly and decently clothed with blooms and foliage. Not liable to mildew, and can stand a little rain as well as most. The blooms come well in clusters, well shaped, of much the same colour as *Safrano* and *Sunset*, but rarely large enough for exhibition. It is wonderful as a free bloomer, the plant being smothered with flowers from top to bottom during the first crop, and a fair amount of blooms, if the plant be in good health, continue into the autumn. It is quite hardy, and to my mind one of the very best of climbing *Roses*. Not so large as *Gloire de Dijon*, nor quite so good as a continual bloomer, early and late, but superior to it in manner of growth for covering a wall.

Solfaterre (Boyau, 1843).—A strong climber, with large open loose blooms of little merit. It is tender, not so good as *Lamarque*, and would probably never have come into use if it had been raised at a later date.

Triomphe de Rennes (Lansereur, 1837).—This old *Rose* is a fair grower, but not strong enough for anything but a dwarf wall. It is a free bloomer, with characteristic wood and habit, but very tender, and easily killed by frost. The blooms require a good deal of heat, and to be protected from rain; they are very fine when you get them good, of most perfect pointed shape, sweet scent, and capable of reaching a full average size. It is quite good enough to show in any company when grown at its best, but we never see it, and this, perhaps the finest shaped of all this section, does not appear in the N.R.S.'s catalogue at all. It is certainly very difficult to grow well, and has probably been more often spoken of than seen during its long existence of fifty-two years.

William Allen Richardson (Ducher, 1878).—Of good growth, but not long enough to be called a climber; not liable to mildew or much

injured by rain. This is a Rose that very soon gained considerable reputation owing to its colour, which is a decided orange, a shade till then unknown in Roses, and even now I believe it is only to be found elsewhere in the centre of Perle d'Or, one of the tiny Polyanthas. I remember being at a Crystal Palace Show, and overhearing a lady inquire of a rising professional grower about W. A. Richardson, which was then a novelty. "Oh! you would not like it," was his reply; "it is very small." It is indeed quite small, and suitable only for button-holes and decorative purposes; but I was sure he had made a mistake, and that the Rose would be much sought after, especially by ladies, and I think I am right in saying that ever since that time I have had more applications for buds for propagating purposes of this Rose than of any other variety. In shape it generally comes well, but it has most provoking manners, which I should think have often caused annoyance, for the blooms often come of a very pale yellow with no trace of orange, except perhaps at the very base of the petals; but about the time that the nurseryman who supplied it has received an indignant letter of complaint the buyer on passing by the plant sees a bud coming of the true colour. For a while they will all come true, and then some come perhaps nearly white again. This is a very provoking habit, and I do not know that the cause of it is understood. I thought at one time it was only the extra strong buds which came of the wrong colour, and it is true the weakest shoots generally produce true flowers, but I am not sure that the weather has not also something to do with it. The blooms come well shaped, and are lovely when they come true to colour. It is fairly free blooming, and pretty good as an autumnal, but requires to be well treated, and though harder than some of the Teas is liable to injury from frost.

TEAS.

The Roses of this charming section are especially liable to the following bad manners:—Impatience of rain and of frost, and of being grown as dwarfs; but these are more than counterbalanced by their good qualities: entire immunity from orange fungus, being almost all free bloomers and good autumnals, lasting better than H.P.'s, and thriving better than they do on light soil.

Adam (Adam, 1833); syn. *President* (Paul & Son, 1860).—Of poor growth and small reputation. The blooms are large, globular, and very sweet, but loose and untrustworthy, and the sort is of little value as a free flowerer or autumnal.

Amazon (Ducher, 1872).—Of rather better growth, with long pointed buds of a good deep yellow colour, which is still much wanted in this class. Some of the Teas are only valued in the bud state for cutting and market purposes, and those that have long slender buds are much more graceful and valuable for decoration and wreaths than the globular sorts. They are useful for this purpose, even if the shape be poor when fully opened. *Amazon* has, however, much helped by its colour, been occasionally shown successfully, notably in the winning professional seventy-two at the last N.R.S. Show at the Crystal Palace. But it is loose and wanting in centre, of no value as a free bloomer or autumnal, and can by no means be reckoned among the best.

Anna Olivier (Ducher, 1872).—A good grower with bright foliage, but the secondary shoots from the base are much stronger than the spring growth; but little liable to mildew, and will do well as a dwarf. All the Teas are liable to be spoiled by rain, the petals sticking together and then decaying. Those which are fullest and stoutest in petal are the worst, and this Rose, being inclined to be thin and not so full as some, does not suffer perhaps so much. The blooms usually come well, it being generally the case with Teas, as with H.P.'s, that the largest and the strongest blooms are the most likely to come "divided," or otherwise malformed. This is a lovely Rose of the charming pointed globular shape, and capable of reaching a full size; it requires to be grown extra strong to be fit for exhibition, but is then very effective. I remember one some years ago in a stand which won the amateur's trophy whose petals were very fine indeed, and seemed unusually stout. But it is not in general a Rose of lasting qualities for a Tea, though its extreme freedom of bloom throughout the season, charming shape in the bud, freedom of growth, and comparative hardiness should give it a place in almost every list.

Bel'e Lyonnaise (Levet, 1869).—See *Gloire de Dijon*.

Bouquet d'Or (Ducher, 1872).—See *Gloire de Dijon*.

Catherine Mermet (Guillot, 1869).—Of moderate growth, with not strong foliage, rather liable to mildew, and easily injured by rain. The blooms as a rule come well, and the amateur who can get a really strong shoot and can keep the bud dry will generally be richly rewarded. This is one of the finest Tea Roses when grown to perfection. It must be strongly fed, and all the power reserved for two or three blooms; then in petal, fulness, shape, size, and lasting qualities it is near perfection, but the colour is more fleeting than the shape. This is one of the varieties which will not succeed as a dwarf, at least with me. I do not know the reason why certain of the Teas, if budded on the Briar close to the ground, do not thrive or flower so well as when budded on the same stock a little higher—18 inches will make a great deal of difference—but so it certainly is with me, and as I cannot keep standard Teas alive in severe frost in my low situation by any protection that I have hitherto tried, this little piece of bad manners is to me especially annoying. A Rose of great reputation, and by many considered highest in merit among show Teas. The raisers of new varieties bear witness to its good name by the readiness they show to class their productions as "in the way of *Catherine Mermet*." But it cannot be called hardy, of strong constitution, free blooming, a good autumnal, or "able to do anywhere."

Comtesse de Frigneuse (Guillot, 1885).—This Rose raised our hopes by its colour, for, as I have said, we want a bright, reliable, decided, self yellow among the pure Teas; but we were doomed to disappointment, as it is loose and most uncertain in shape, and not even long and fine in the bud like *Amazon*.

Comtesse de Nadaillac (Guillot, 1871).—Of dwarf, thorny, and, unless well treated, weakly growth and foliage; not liable to mildew, but spoiled by rain, though more tolerant of it than some. This is a Rose which, despite its small growth and generally feeble appearance, rises in reputation every year, and was last season very much ahead of all show Tea Roses. The habit of this variety and that of *Princess of Wales*, is, as I tried to show lately in the *Journal*, peculiar to themselves. The smallest shoot with a little bud at the end may grow and swell for weeks before opening, and will then probably show a bloom that not only for beauty but also for size will utterly eclipse anything that can be produced from even such strong rampant growers as *Gloire de Dijon* or *Climbing Devonensis*. Six or seven years ago I had a very small plant of this Rose. It had made hardly any growth the previous season, and, when pruned, there remained the crooked Briar stem about 10 inches high, and as thick as one's finger; above that about 2 inches of old wood, and at the end of this a tiny stump of new wood. Two buds pushed very early, resulting in two weakly looking shoots, each with a bud at the end. The season was hot, and the plant stood in a border near a short south wall. Instead of these buds opening in the great sun heat they simply grew and swelled for some weeks, the shoots thickening in proportion. One of the buds opened several days before the first available show. After being admired for a day or two it was cut as hopeless to keep for show purposes, and placed in water in the house for three days, and yet was the best bloom in a winning stand of twelve on the fourth day. The other bud opened a week later, and was exhibited at three shows. At the first it won the prize as the best Tea, at the second the silver medal as best Rose (H.P. or T.) in the show, and at the third, where no prize was given for a best Rose of any sort, it was still one of the most noticeable in a winning stand of twelve. And yet a thick strong bushy shoot may open its bud almost at once, and produce a comparatively poor bloom. It does decidedly best as a short standard, but will also yield fine flowers as a dwarf. The blooms sometimes come divided, but when good they are first rate in petal, fulness, shape, lasting qualities, and size. The colour is lovely and most changeable. Mr. Prince can show it as a yellow Rose, but this is generally when it is too much expanded, and the "point" is gone. There is much more pink than yellow in it with me. The plants are of pretty good constitution, by which I mean that they will live and not deteriorate for many years if well cultivated, will stand close pruning, and may be planted pretty near together. Being of such small growth it cannot of course stand high in estimation as a free flowerer or autumnal, and it is often difficult to find a sufficiency of good buds for propagating purposes.—W. R. RAILLEM.

(To be continued.)

MARÉCHAL NIEL CANKERING.

I LOOK forward each week to Mr. Raillem's catalogue commentary. It is most useful and interesting, but I was astonished to read this morning the assertion from so able and experienced a grower that "there is no cure for canker" in *Maréchal Niel*. Now I have grown this Rose for many years, but I never lost a plant from canker. I think the eyes of rosarians must be blind or their hearts hardened against the poor plant's plaintive and touching cries for help if they do not see and use the remedy. Why does this Rose canker? Surely from a check to the flow of sap. Nature sometimes causes the bark to crack and so temporary relief is afforded, which assistance may be made complete and permanent by cutting with a sharp knife deeply through the canker and continuing the cut down below the ground line. I have seen scratches of a knife, evidently made in doubting unbelief, quite ineffectual, but where the cut has been made boldly and continuously the result has been a new formation of bark, a regular flow of sap, and immediate thanks from the grateful plant in the shape of vigorous shoots and abundant blooms. Bob Sawyer's remedy of hot punch for rheumatism failed, as he said, only when the patient fell into the vulgar error of not taking enough of it. *Maréchal Niel* will die of canker only from the dread of the operator to use his knife with a free and continuous cut. I hope someone else may tell us of a quicker and safer remedy. Don't say "there is no cure for canker" in *Maréchal Niel*.—HENRY B. BIRON, *Lympne Rectory, Hythe*.

MILDEW ON ROSES.

How to prevent this is a perplexing question with many, and any information is sure to be of interest to some of your readers who grow Roses under glass. Two good-sized span-roof houses at Highbury, near Birmingham, the residence of the Right Hon. Joseph Chamberlain, M.P., are devoted entirely to Roses in pots and planted out, and are now in excellent health and showing plenty of flowers, and are entirely free from mildew. Mr. Cooper keeps the hot-water pipes well supplied with a dressing of black sulphur, and to this cause he attributes the absence of mildew.—D. S. H.

AMONGST THE PRIMULAS.

FOR many years Messrs. J. Carter & Co. have annually had a display of Primulas in their Perry Hill Nurseries that well merited inspection, but the exhibition at present provided surpasses in most respects all their

previous efforts. Six span-roof houses are filled with plants in flower, the total number exceeding 6000, and all the varieties being arranged in their respective colours, a bright and effective display is the result. Large quantities of seed are required to meet the demands, and it is only by devoting special attention and much space to this work that the requisite supplies can be secured and the quality of the varieties or strains fully maintained. The latter is an essential portion of the proceedings, and no efforts are spared to preserve the distinctions already fixed, and to obtain meritorious novelties. An inspection of the Perry Hill plants affords satisfactory evidence of the success that has attended the exertions of the firm in both the respects named.

In plants that are grown for seed-bearing purposes one of the points that has to be avoided is excessive vigour. It is comparatively easy to have a plant in market condition, distinguished by luxuriant growth, large leaves, and huge trusses of flowers, but to have one in perfect health, yet free from all coarseness, is altogether different. Those who are experienced in seed-saving know quite well that more abundant and certain crops are attained from hardy firm-foliaged plants of medium growth than from their more luxuriant relatives. Recognising these facts the Manager at the Perry Hill Nursery always has the plants in 48-size pots, avoiding a larger size lest too much root space should induce an undesirable growth. The wisdom of this course is proved by the even character of the plants, their uniform health, the stout texture of the flowers, and the clearness of the colours. It might be added that well developed and properly matured seed is also more readily obtained from such plants, and the importance of this point all who are concerned in raising *Primulas* from seed for decorative purposes will at once recognise.

All the varieties in the collection cannot be enumerated, especially as one house is devoted to experimental crosses which have resulted in numbers of new varieties, the best of which are selected for further experiments and seeding purposes. Some, however, amongst the proved type deserve mention, and of singles *Holborn Vermilion* is one of the best high-coloured forms yet raised. The tint is well expressed by the name, and in contrast with white or light-tinted varieties it has a capital effect. *Holborn Ruby* and *Magenta* are two other handsome varieties of peculiarly rich shades of colour. *Holborn Salmon* is distinct and delicate, *Elaine* is fittingly described as "Ivory White," and "Pearl" is a pleasing white flower shaded with the faintest blue-grey hue. A great advance has been made with the single blue *Primulas*, and a variety is notable for the size, substance, and deep colour of its flowers.

The double varieties everyone values, and prominent amongst them are *Snowflake*, pure white; *Prince of Wales*, rich crimson; *Carmine Empress*, an extremely rich colour; and the *Double Blue*.

The varieties named are only a few selections, there are many others nearly equally good, and several interesting forms that are likely to yield something of a very novel character. The *Gold Leaf* is one of the most peculiar of these, with foliage of a clear yellowish tint, but it has been found difficult to raise a stock of them up to the present. Another is called "*Picotée-edged*," the flower having a mauve pencilling at the margin, while the "*Yarrow-leaved*" is remarkable for the finely cut character of the foliage.—X.

CATERPILLARS AND FRUIT TREES.

CONFERENCE AT EVESHAM.

THE CATERPILLAR BLIGHT.

A CONFERENCE of those immediately interested in preventing the ravages of insect pests in their relation to the market gardening industry took place at the Town Hall, Evesham, on Wednesday afternoon. The Mayor (Alderman Masters) presided, and there was a fair attendance, among those present being Messrs. C. D. Wise (Toddington), T. W. Beach (Brentford), A. E. Brach (Toddington), J. Hiam (Astwood Bank), W. W. Brown, G. Hunt, T. J. Slatter, Malleson (Toddington), De Laune (Toddington), T. E. Doeg, Harvey Hunt, G. Hughes, A. Watkins (Aldington), F. Hooper, J. H. Pumphrey, C. Ward, J. Lunn, Pentin (Toddington), Clare (Toddington), Eean (Offenham), &c. After the reading of correspondence between the Mayor and Miss Ormerod relative to moths which attack fruit trees, the use of Paris green, the strawsoniser, &c.,

Mr. J. HIAM placed before the assembly a collection of moths and apparatus for the destruction of caterpillars on fruit trees, &c., and proceeded to read a paper on "Moths Injurious to Fruit Trees." In doing so he said he had brought with him a few of those moths which the Mayor had referred to, and the first was the Winter Moth. (Here a box was handed round containing a number of male and female members of the family of Winter Moths, together with some thousands of eggs which had been deposited since the capture of the moths.) The number, he said, included specimens of the *Cheimatobia brumata*. He had also specimens of the Mottled Umber Moth, or Great Winter Moth. These were not very common, but they were very destructive, and it appeared that they laid about 400 eggs each, while it was reported that the smaller ones only laid 200 eggs. They would see that the Great Winter Moths were more destructive than the others from their numbers, but from some cause or other they did not accumulate to the same extent as the smaller tribe. He only met with one specimen in the autumn of 1888, and about half a dozen in the autumn of 1889. One specimen of the small moth was taken early in November, which was compared with Mr. Whitehead's drawing on page 19 of his pamphlet for 1888, and was identical. The Lackey Moth

caterpillars which Miss Ormerod mentioned were very troublesome in some localities in the summer of 1888; one colony was cut out complete, and was found to contain eighty-three caterpillars. Their tent-like nest was very conspicuous and interesting, and the methodical habits of the caterpillars were interesting to watch. The small *Ermine* Moth caterpillars were easily detected in groups, and easy to distribute and destroy. On the least disturbance they would descend by a fine thread or web, and might easily be caught and destroyed. The grubs of the Codlin Moth, which might be found on Apple trees, had become troublesome of late years so far as they could be, but it would be interesting to note what became of them another season should there be any fruit. From the scarcity of Apples last year the grubs could not, of course, develop in the Apples in their natural way, and might on that account have become nearly or quite extinct. They laid their eggs on the fruit and eat their way through.

Mr. GEORGE HUNT: If they could not find an Apple, could not they live on something else?

Mr. HIAM: Not that particular moth. Proceeding, he said that the caterpillar of the same moth lay in the chrysalis state on the trunks of the trees, and the only way in which he thought they could destroy them would be by washing, or encasing the trunks of the trees with thick limewash. (Mr. Hiam now exhibited a small portion of a tree branch washed with a composition of lime, cowdung, and softsoap, and which he considered would encase the caterpillars; but a thicker casing than the one exhibited would be necessary in the case of the Codlin Moth.) There was a species of the Leaf-rolling Caterpillar which was particularly troublesome, and which was very numerous, especially on wall fruit trees. They were almost as bad as the ordinary Winter Moth. He had some specimens in confinement, but the moths had since been destroyed. Mr. Hiam now presented specimens of the Gooseberry Sawfly, which he said was responsible for all the damage done to the Gooseberry plantations. Proceeding to speak of the methods for destroying chrysalis, he said that doubtless some good would result from hoeing and turning over the soil under fruit trees. Paring and burning would be expensive, and also, to some extent, detrimental to the fine fibrous roots near the surface. Where practicable he would prefer penning hens and chickens on the ground. These doubtless would be of much value, besides turning the pests to use as food. These pens might be often moved, and they could thus soon go the round of an orchard. The fowls should be kept short of food to encourage them to scratch. He regarded the methods of intercepting moths in their ascent to deposit their eggs as the most important subject of all. He was so thoroughly convinced of the utility of the grease banding, if properly and efficiently carried out, that he paid very little attention to the hoeing, &c. Where failure had occurred he was satisfied that the workmanship or the material was at fault. To avoid such failures in the future was the aim and object of his introduction of the patent barriers, on which the grease might be applied without unsightliness or fear of failure through absorption, or from wet or frost, and no danger to the life or health of the tree was to be feared. The latter objection was a great detriment to many from using the applications of grease, and the fear had in some cases been well grounded. To prevent the moths getting past the barrier where it joined the tree he proposed to wind some soft material round the tree before placing the barrier. This soft material would prevent injury to the tree, and would also prevent the moths getting past.

Mr. HARVEY HUNT: Would not that method be expensive?

Mr. HIAM: No, not with common tin or zinc. The crop of the first year would pay for ten or twenty such bands.

Mr. G. HUNT: But the trees are of different sizes.

Mr. HIAM explained that the barriers could be made in gradually increasing sizes. He did not think that the smaller sizes would cost more than 1d. each.

The MAYOR (alluding to a large size): What is the cost of that?

Mr. HIAM: I don't think they would cost 3d. taken in quantities; it would be a poor tree that did not produce threepenny-worth of fruit. The prospects of the future would be better, and the economy sure. They suffered very much damage from earwigs, and this method would prevent their ascent of the trees. At this point the speaker produced a bottle containing 2750 earwigs, which he explained were the produce of his orchard last year. At one time he was not aware of the damage which earwigs could do, particularly to Apples. They ate little holes not larger than pin holes in the Apple; that hole gradually became rotten, and when Apples were placed in quantities together decay gradually took place, and ultimately the whole mass became rotten.

The MAYOR: Do you think one daub of grease on the band would be sufficiently effectual?

Mr. HIAM: Yes, if it is put on thick enough. Proceeding, he said as to the destruction of caterpillars in the fruit trees he had read Miss Ormerod's reference to the strawsoniser with very much interest, and so far as could be gathered without seeing the machine in operation and the effects of the poison, it seemed very feasible that a vast amount of injury to fruit trees by caterpillars would be prevented by its use. There were several questions which naturally arose as to its adaptability to fruit plantations in the Evesham district, where undercropping with vegetables was carried out to a great extent. First, Could a horse be driven through such plantations without doing a great amount of damage? and if so, would it be possible to use poison among such vegetables as Cabbages, Lettuce, Asparagus, &c., and without danger to health? In May Gooseberries would be getting fit for market, and

would it be safe to use poison, or Paris green, as it was called? Another question was as to the evenness of the ground for getting about with a vehicle or machine on wheels over, for instance, Asparagus beds? The cost of a machine would also be a great deterrent, except to very large fruit growers. His idea of meeting the question of caterpillars on his own trees was to watch most carefully in April for their first appearance, as a few would doubtless have escaped the deathly bands before the application of the latter. He was of opinion that a sudden violent shaking would dislodge them even in a young state, and to prevent their re-ascent he would apply a little fresh dressing in a thinner state than that used for the destruction of the female moth. He was more sanguine of the efficacy of this method from having caught 750 spiders on one band. It would be advisable to repeat the shaking process at intervals from the end of October to the end of December. He had no fear about the state of the majority of his trees. He had neglected a few small ones, which he felt he could go over very easily. (Applause.)

EXPERIMENTS ON LORD SUDELEY'S FRUIT FARMS.

At the instance of the Chairman, Mr. C. D. WISE then read extracts from a paper which he had prepared. He said that in Captain Corbett's absence he was very pleased to give them any information as to the methods they adopted at Toddington against the spread of the blight, and also as to the success they had met with. In the first place, to come to the point at once, he would take the Evesham or winter moth. As they all knew, of course, the female moth which laid the eggs was wingless, and that it was necessary for her to ascend the stem of the tree. One thing they had to decide was the right time to put the bands on if they put them on at all, and how long should they be kept sticky—should they be put on on the 1st of October or the 1st of November, or when? They found by comparing notes for the past three years at Toddington that the bands should not be put on later than the first week in October. In 1888 they commenced banding on October 16th, and caught the first moth on October 18th. That was too late, and it showed that the moth might be earlier or later according to the season. This year they caught the first moth on October 7th. That showed that the bands should not be put on later than the first week in October. This winter they were catching moths on the bands at Toddington on December 16th, and that showed that to catch the first hatch the bands should be kept sticky until December 31st. With regard to the grease, in 1887 they used a ready-made mixture, and in 1888 they made their own stuff, which was composed of 1 gallon of Stockholm tar to 1 cwt. of grease, and they also used ordinary cart grease.

THE TREES DAMAGED.

They found without doubt that all these mixtures were injurious to the young trees, and in fact none of their trees were more than ten years old, and many only three or two years, so they determined not to use them again. He had found trees alive up to the band and dead above it, and he thought that was pretty good proof.

The MAYOR: Does that apply to young trees only?

Mr. WISE: To young trees particularly; none of ours are more than ten years old. There was no doubt that the tar formed a sort of hard band round the tree and stopped the flow of the sap, and water-proofed the cells. It was also a question whether it would not soak into the bark and become distributed in the sap. When the trees had resisted the grease he found the bark cracked and peeled off, so that if another band were put on in the same place it would no doubt greatly injure the tree, if not kill it. If it were put lower down it would be extremely dangerous. Then, again, grease was sure to soak into the bark of a young tree to a great extent. They had had the grease they used analysed, and had as yet been unable to find any which would not injure the trees. One they had used was as follows:—"The grease consists of two oils mixed with water and superphosphate of lime." The tar no doubt did the mischief. Taking all that into consideration they determined to put a band of paper on the trees, and the grease on that, and he showed specimens. The paper cost about 10s. a cwt. It was grease-proof paper, and was procured from Messrs. Adlard & Evans. The paper was ready cut to put on the trees, and one ream would do 247 trees, one sheet would do six trees, and 1 lb. of grease would do six trees. The work was chiefly done by women and boys. One woman with a basket and a pot of paste wrapped the paper round the tree and pasted the lap, and was followed by one who tied a piece of matting round the lower end of the band and could also grease it. In this way two good women could do 200 trees a day.

Mr. HOOPER asked if the tree had a rough bark, whether the moth would not crawl under the paper.

Mr. WISE replied that the piece of matting tied round the bottom of the band prevented that. In answer to the Mayor he said that he thought that in that way grease would be saved. He thought that the grease should be removed every three weeks or so, and the bands should be kept sticky at least up till Christmas. He found a moth on December 17th last year. Now they came to the question as to how, having taken all that trouble, they found caterpillars in the spring. One way in which they were beaten was that the male moth carried the female up into the trees, and deposited her in the branches. Miss Ormerod thought this was done more than was generally supposed. Another point to consider was, Were the eggs laid in stems of the trees below the grease band fertile? He found some eggs last spring, and they sent some to Miss Ormerod, and asked whether they were fertile, and in her reply she said the eggs appeared alive in many instances, and in one she found the indication of the segment of a caterpillar, and from that she

thought they might consider a sufficient quantity of eggs was alive and needed looking after. She recommended a second application of grease bands or dressing the trees with softsoap, &c. He considered that from continual greasing the moth was decreasing. In consequence of what Miss Ormerod said they got some hard scrubbing brushes, and scrubbed each tree with a mixture of tempered clay, soot, lime, cowdung, and water, and they would do the same again in the spring. Not only did it destroy the eggs, but it had a beneficial effect on the trees in cleaning the bark. Mr. Fletcher, the Dominion Entomologist of Canada, in a letter to Capt. Corbett, recommended kerosene emulsion to be applied at the end of March. The emulsion should be made of various strengths according to the age of the trees. The following was the ordinary strength:—One pint of kerosene (or refined coal oil), half ounce of common soap, half pint of rain water; the soap to be boiled in the water till all was dissolved, and the kerosene to be churned up in it. If these were used for spraying they must add nine times the quantity of water. They found that in pruning young trees a great quantity of eggs were destroyed, but the prunings should not be left about the gardens, or else the eggs would hatch. They took them all away and burnt them. They then came to the question of greasing in the spring to catch late comers. Last year they greased on March 2nd in case any caterpillars should hatch in the Currant bushes, and find their way up the Plum trees, but they caught very few. He did not think it paid to do, but should be glad to hear some practical opinion on the point.

NO MORE SHAKING.

As regarded the caterpillar when it hatched, supposing they had not greased, and their trees were covered with them, what was to be done? Shaking was not much good if they had bush fruits under. They tried that in a plantation that was badly attacked, but they shook them on to a sheet and caught thousands, and they shook them on to the Black Currants, and they attacked them, and they even tackled the Strawberries. If there were grass underneath the trees, shaking might be useful.

Mr. LUNN asked if those trees had been greased?

Mr. WISE replied that he was speaking of three years ago.

Mr. HARVEY HUNT asked whether the caterpillars came in the shape of blight on the wing?

Mr. WISE: No, certainly not. The only way in which the wind affects the growth is that it hatches them more quickly sometimes. Proceeding, he said the caterpillar immediately on hatching ate its way into the nearest bud, and there remained until the bud opened, by which time it had grown considerably. The time to kill by washing was when it first hatched, but the difficulty was to catch it at the right moment. What they wanted was a wash that would kill it after the leaves were out. They had tried everything they could think of. They had tried paraffin and softsoap, but with paraffin care was necessary. They used one pint to three gallons of water as an experiment, and killed the tree, but he thought the reason the tree was killed was because the paraffin was not properly mixed with the water. No doubt several solutions would kill the caterpillar if they could get at it. They had tried two ounces of softsoap boiled in one gallon of water, and a quarter of a pint of paraffin added, and they found that if they held a branch in it the caterpillars were killed, but syringing a tree with it did very little good apparently. Common soda was tried, first fourteen ounces to three gallons of water. This killed the caterpillars, but shrivelled up all the leaves and fruit. Then they tried eight ounces to three gallons of water, which slightly burnt the foliage but did not kill the caterpillars. But then the caterpillars were nearly full grown, and what the result would have been had it been tried before he could not say. They had also tried other things. Mr. Fletcher had written a letter to Captain Corbett, in which he stated that he was under the impression that the most satisfactory mode of treatment would be to spray about the tree with some preparation of arsenic. For his part he preferred Paris green as being the most uniform in quality. The chief thing to be guarded against was getting the liquid too strong. He went on to express his opinion that the only successful treatment was spraying on the trees just when the caterpillar was hatched. Fumigation was also recommended. Mr. Wise mentioned that last spring they were burning a road through one of the largest plantations, and there they had a very large crop of fruit indeed. He did not know whether the smoke had anything to do with it.

Mr. T. W. BEACH believed it had a great deal to do with it. A number of small fires in a plantation did a great deal of good. Mrs. Wallace always made a point of burning all refuse during the time the trees were in flower.

USE OF PARIS GREEN.

Mr. WISE, continuing, said spraying should, he thought, be done between the 14th and 30th of April, and if done then he did not think any fear need be occasioned by the use of Paris green where they had Currants, Raspberries, Gooseberries, or Strawberries, as these fruits would not have advanced enough to be contaminated, but in the case of vegetables it was a different matter. Miss Ormerod had given him some valuable information as regarded Paris green. She said that from 2 to 4 ozs. in forty gallons of water was recommended for the Looper or Codling Moth caterpillar. That was about the same quantity recommended by Mr. Fletcher. She pointed out that the proportion of arsenic would be so minute (only about 1 oz. in forty gallons of water) to an area of about an acre of flat leafage that it seemed to her impossible that any ill results could arise from the poisonous nature of the application to human health. He thought they should give that a trial,

using great care and judgment in the use of it. In conclusion Mr. Wise expressed pleasure that that meeting had been held, and said that what was necessary was that they should meet together, and tell each other the results of their experiments. (Hear, hear). In support of this he had received a letter from Miss Ormerod, in which she expressed the opinion that some arrangement might be made by which meetings might be held and experiments made. She would be glad to act as entomologist, and would be happy to subscribe £10 to the object. (Applause).

A MOTH TRAP.

MR. T. W. BEACH then exhibited a lamp which was designed to catch the male moth. This was lighted at night, and a large shade at the top, and similar projection at the bottom, were well greased. The result is that when a moth flies against the glass it either flies up or down, and in either case is caught. This lamp, Mr. Beach explained, has been found very useful on dark nights.

A COMMITTEE FORMED.

The MAYOR said he did not think it would be wise for them to prolong that meeting, as they had an important meeting in the afternoon. He, however, had a resolution to read to them. It was to the effect that a Committee of six fruit growers from different localities should be appointed to make experiments and report to the future Conference, and that Miss Ormerod's offer to act as entomologist and her promised donation be gratefully accepted. — (*Evesham Journal*.)

HARDY FRUIT GARDEN.
